EXCLUSIVELY COMMITTED TO LINEAR

The founding theme of Linear Technology Corporation was to create a company capable of leading and directing linear circuit technology and design concepts of the future, and thus become the market's linear specialist. The company believes that the total IC business has become so diverse and so complex that a single company will have great difficulty assembling the engineering talent necessary to lead in all areas of device technology.

Today, the customer base benefits by accessing the best product available in each functional area of the IC market from those vendors who are at the leading edge of performance and technology as a result of their "focused" strategy approach. The customer now has the choice of acquiring the best linear, the best microprocessor, the best memory products, etc., by choosing the best vendor in each area. In order to achieve the goal of becoming the market's first choice in the linear area, LTC has assembled the leading design, test, product, assembly, quality and process engineering talent in the industry, operating in what we feel is the most modern linear integrated circuit facility in production today.

Linear Technology possesses a wide variety of bipolar processes including Super Beta, Bifet, low noise, high speed, thin film resistors, sinkers, sub-surface zeners, and more. The company also has in production a very modern silicon-gate CMOS process, LTCMOS™, which is specifically tailored to satisfy the special needs of linear IC functions.

Linear Technology is committed to servicing the demanding requirements of the Military/Aerospace marketplace. Our 883 program is designed to consistently provide off-the-shelf high performance linear integrated circuits tested to the requirements of MIL-STD-883 Class B, and fully compliant to Revision C. Our documentation, designs, procedures, and facilities have been carefully established to meet the rigid requirements of MIL-STD-38510 level devices. The company's facility is JAN approved and numerous JAN QPL part types are currently being supplied by Linear Technology. All military-grade products are 100% tested at temperature extremes. Both commercial and military outgoing quality levels are sampled over temperature with full lot traceability back to the original wafer from which the device was derived. Presently Linear Technology can boast that its products are used by all of the top 25 largest military contractors in the U.S.

On the commercial side of the business, the company's proprietary products are currently being used by leading manufacturers of automobiles, computers, instruments, cameras, telecommunication systems and in many other areas. The company prides itself in doing business with the major manufacturers and leaders in each of these market segments.

This catalog contains products that already enjoy very wide acceptance status in new and existing end products.

In addition to the commitment to provide better technical solutions, we also commit to our customers that we will strive to make quality and reliability a reason to buy from Linear Technology. Our products address the instrumentation, industrial, data acquisition, peripheral, interface, and military markets with solutions to linear systems application problems.

EXCLUSIVELY COMMITTED TO LINEAR

The founding theme of Linear Technology Corporation was to create a company capable of leading and directing linear circuit technology and design concepts of the future, and thus become the market's linear specialists. The company believes that the total IC business has become so diverse and so complex that a single company will have great difficulty assembling the significant talent necessary to lead in all areas of device technology.

Linear's customer base benefits by receiving the best product available in each functional area of the IC market from those vendors who are at the leading edge of performance and technology as a result of their "linear focus." Linear's commitment to the customer is to provide the best microcircuit available in order to achieve the best microcircuit performance in each area. In order to achieve this, Linear Technology Corporation has assembled the leading design and engineering talent in the industry, operating in what we feel is the most integrated circuit facility in production today.

Linear Technology possesses a wide range of design and production facilities including Super Beta 8000 not only high speed thin film resistors, surface mount devices, and more. The company also has in production a very modern silicon-gate CMOS process, L7CMOSTM, which is especially tailored to satisfy the specific needs of linear IC functions.

Linear Technology is committed to providing the demanding requirements of the military marketplace. Our 283 program is designed to deliver a consistently superior off-the-shelf high performance linear integrated circuit series to the requirements of MIL-STD-883 Class B, and fully compliant to Revision C. Our documentation, design, production, and facilities have been carefully established to meet the high requirements of MIL-STD-883 level devices. The company's facility is JAN approved and numerous JAN DFP parts are currently being supplied by Linear Technology. All military-grade products are 100% tested at temperatures between both commercial and military outgoing quality levels. The standard over temperature with full lot traceability back to the original water flow which the device was produced. Linear Technology can assure that the products are used by all of the top 25 largest military contractors.

LIFE SUPPORT POLICY

LINEAR'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF LINEAR TECHNOLOGY CORPORATION. As used herein:

- Life support devices or systems are devices or systems which (1) are intended for surgical implant into the body, or (2) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user.*
- A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.*

Information furnished herein by Linear Technology Corporation is believed to be accurate and reliable. However, no responsibility is assumed for its use. Linear Technology Corporation makes no representation that the interconnection of its circuits, as described herein, will not infringe on existing patent rights.

INDEX	1-2
GENERAL ORDERING INFORMATION	1-3
ALTERNATE SOURCE CROSS-REFERENCE GUIDE	1-4
PACKAGE CROSS-REFERENCE GUIDE	1-11

I. ORDERING INFORMATION

Linear Technology employs numerous sales representatives, stocking distributors and stocking representatives, throughout the world. For a list of the distributors nearest your location, please contact Linear Technology in Milpitas, California. Local inventories and pricing of Linear Technology products are generally available through these distributors.

Orders placed directly with the factory require a minimum order value of \$2000.00, and a minimum line item value of \$500.00. Terms are net 30, FOB Milpitas, California.

II. RELIABILITY PROGRAMS

Linear Technology Corporation currently offers the following Reliability Programs:

- A. JAN QPL devices.
- B. DESC drawings.
- C. Mil-Std 883, Level B, Revision C for all military temperature range devices.
- D. "R-Flow" Burn-In Program for commercial temperature range devices. Consult Factory regarding burn-in program.

III. PART NUMBER EXPLANATION

IV. PACKAGE SUFFIX EXPLANATION

Letter Designator	Description
D	14, 16, 18 and 20 Pin Side Brazed Hermetic DIP
D8	8 Pin Side Brazed Hermetic DIP
H	Multi Lead Metal Can
J	14, 16, 18 and 20 Pin Ceramic DIP
J8	8 Pin Ceramic DIP
K	TO-3 Metal Can (Steel)
N	14, 16, 18 and 20 Pin Molded DIP
N8	8 Pin Molded DIP
T	TO-220 Molded (3 lead, 5 lead)
Z	TO-92 Molded (3 lead)
S8	8 Lead Small Outline (SO) Package

- **Low Power Dissipation**

LT1001AM	75mW max
LT1001C	80mW max
- **Low Noise 0.3 μ V_{p-p}**

APPLICATIONS

- Thermocouple amplifiers
- Strain gauge amplifiers
- Low level signal processing
- High accuracy data acquisition

DESCRIPTION

The LT1001 significantly advances the state-of-the-art of precision operational amplifiers. In the design, processing, and testing of the device, particular attention has been paid to the optimization of the entire distribution of several key parameters. Consequently, the specifications of the lowest cost, commercial temperature device, the LT1001C, have been dramatically improved when compared to equivalent grades of competing precision amplifiers.

Essentially, the input offset voltage of all units is less than 50 μ V (see distribution plot below). This allows the LT1001AM/883 to be specified at 15 μ V. Input bias and offset currents, common-mode and power supply rejection of the LT1001C offer guaranteed performance which were previously attainable only with expensive, selected grades of other devices. Power dissipation is nearly halved compared to the most popular precision op amps, without adversely affecting noise or speed performance. A beneficial by-product of lower dissipation is decreased warm-up drift. Output drive capability of the LT1001 is also enhanced with voltage gain guaranteed at 10 mA of load current. For similar performance in a dual precision op amp, with guaranteed matching specifications, see the LT1002. Shown below is a platinum resistance thermometer application.

Linearized Platinum Resistance Thermometer

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Offset voltage for the LT1001AM/883 and LT1001AC are measured after power is applied and the device is fully warmed up. All other grades are measured with high speed test equipment, approximately 1 second after power is applied. The LT1001AM/883 receives 168 hr. burn-in at $125^\circ C$. or equivalent.

Note 2: This parameter is tested on a sample basis only.

Note 3: Long Term Input Offset Voltage Stability refers to the averaged trend line of V_{OS} versus Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 days are typically $2.5\mu V$.

Note 4: Parameter is guaranteed by design.

Note 5: 10Hz noise voltage density is sample tested on every lot. Devices 100% tested at 10Hz are available on request.

APPLICATIONS INFORMATION

Application Notes and Test Circuits

The LT1001 series units may be inserted directly into OP-07, OP-05, 725, 108A or 101A sockets with or without removal of external frequency compensation or nulling components. The LT1001 can also be used in 741, LF156 or OP-15 applications provided that the nulling circuitry is removed.

The LT1001 is specified over a wide range of power supply voltages from $\pm 3\text{V}$ to $\pm 18\text{V}$. Operation with lower supplies is possible down to $\pm 1.2\text{V}$ (two Ni-Cad batteries). However, with $\pm 1.2\text{V}$ supplies, the device is stable only in closed loop gains of $+2$ or higher (or inverting gain of one or higher).

Unless proper care is exercised, thermocouple effects caused by temperature gradients across dissimilar

metals at the contacts to the input terminals, can exceed the inherent drift of the amplifier. Air currents over device leads should be minimized, package leads should be short, and the two input leads should be as close together as possible and maintained at the same temperature.

- **Low noise 0.35 μ V p-p**

APPLICATIONS

- Thermocouple Amplifiers
- Strain Gauge Amplifiers
- Low level signal processing
- Medical instrumentation
- Precision dual limit threshold detection
- Instrumentation amplifiers

DESCRIPTION

The LT1002 dual, matched precision operational amplifiers combine excellent individual amplifier performance with tight matching and temperature tracking between amplifiers.

In the design, processing, and testing of the device, particular attention has been paid to the optimization of the entire distribution of several key parameters and their matching. Consequently, the specifications of even the low cost commercial grade (the LT1002C) have been spectacularly improved compared to presently available devices.

Essentially, the input offset voltage of all units is less than 80 μ V, and matching between amplifiers is consistently better than 60 μ V (see distribution plot below). Input bias and offset currents, channel separation, common mode and power supply rejections of the LT1002C are all specified at levels which were previously attainable only on very expensive, selected grades of other dual devices. Power dissipation is nearly halved compared to the most popular precision duals, without adversely affecting noise or speed performance. A by-product of lower dissipation is decreased warm-up drift. For even better performance in a single precision op amp, refer to the LT1001 data sheet. A bridge signal conditioning application is shown below. This circuit illustrates the requirement for both excellent matching and individual amplifier specifications.

The ● denotes the specifications which apply over the full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Offset voltage measured with high speed test equipment, approximately 1 second after power is applied.

Note 2: This parameter is tested on a sample basis only.

Note 3: Long Term Input Offset Voltage Stability refers to the averaged trend line of V_{OS} versus Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 operating days are typically $2.5\mu V$.

Note 4: Parameter is guaranteed by design.

Note 5: 10Hz noise voltage density is sample tested on every lot. Devices 100% tested at 10Hz are available on request.

Note 6: The $V+$ supply terminals are completely independent and may be powered by separate supplies if desired (this approach, however, would sacrifice the advantages of the power supply rejection ratio matching). The $V-$ supply terminals are both connected to the common substrate and must be tied to the same voltage. Both $V-$ pins should be used.

MATCHING CHARACTERISTICS at $V_S = \pm 15V$, $T_A = 25^\circ C$, unless otherwise noted

APPLICATIONS INFORMATION

The LT1002 dual amplifier may be inserted directly into OP-10, OP207, OP227 sockets with or without removal of external nulling potentiometers.

Offset Voltage Adjustment The input offset voltage of the LT1002, and its drift with temperature, are permanently trimmed at wafer testing to a low level. However, if further adjustment of V_{OS} is necessary, nulling with a 10k or 20k potentiometer will not degrade drift with temperature. Trimming to a value other than zero creates a drift of $(V_{OS}/300) \mu V/^{\circ}C$, e.g. if V_{OS} is adjusted to $300 \mu V$, the change in drift will be $1 \mu V/^{\circ}C$. The adjustment range with a 10k or 20k pot is approximately $\pm 2.5mV$. If less adjustment range is needed, the sensitivity and resolution of the nulling can be improved by using a smaller pot in conjunction with fixed resistors. The example has an approximate null range of $\pm 100 \mu V$.

In matching applications, both amplifiers can be trimmed to zero, or the offset of one amplifier can be trimmed to match the offset of the other. Offset adjustment, however, slightly degrades the gain, common-mode and power-supply rejection match between the

two op amps. Fortunately, the guaranteed offset voltage match of the LT1002 is very low, in most applications offset adjustment will be unnecessary.

Standard Adjustment

Improved Sensitivity Adjustment

APPLICATIONS INFORMATION

Test Circuit for Offset Voltage and its Drift with Temperature

This circuit is also used as the burn-in configuration for the LT1002, with supply voltages increased to $\pm 20V$, $R1 = R3 = 20k$, $R2 = 200\Omega$, $A_V = 100$.

Unless proper care is exercised, thermocouple effects, caused by temperature gradients across dissimilar metals at the contacts to the input terminals, can exceed the inherent drift of the amplifier. Air currents should be minimized, package leads should be short, the two input leads should be as close together as possible and maintained at the same temperature.

Channel Separation

This parameter is defined as the ratio of the change in input offset voltage of one amplifier to the change in output voltage of the other amplifier causing the offset change.

At low frequencies the LT1002's channel separation is an almost unmeasurable 148dB. As frequency increases, pin to pin capacitance of the package, between the output of one amplifier and the inputs of the other, becomes dominant. Since these pins are non-adjacent, the capacitance is only 0.02pF. To maintain the LT1002's excellent channel separation at higher frequencies, the socket and PC board capacitances should be minimized.

0.1Hz to 10Hz Noise Test Circuit

(Peak to Peak noise measured in 10 Sec interval)

Power supplies

The LT1002 is specified over a wide range of power supply voltages from $\pm 3V$ to $\pm 18V$. Operation with lower supplies is possible, down to $\pm 1.2V$ (two Ni-Cad batteries). However, with $\pm 1.2V$ supplies, the device is stable only in closed loop gains of $+2$ or higher (or inverting gain of one or higher).

The $V+$ supply terminals are completely independent and may be powered by separate supplies if desired (this approach, however, would sacrifice the advantages of the power supply rejection ratio matching). The $V-$ supply terminals are both connected to the common substrate and must be tied to the same voltage. Both $V-$ pins should be used.

APPLICATIONS INFORMATION

Advantages of Matched Dual Op Amps In many applications the performance of a system depends on the matching between two operational amplifiers rather than the individual characteristics of the two op amps. Two or three op amp instrumentation amplifiers, tracking voltage references and low drift active filters are some of the circuits requiring matching between two op amps.

The well-known triple op amp configuration illustrates these concepts. Output offset is a function of the difference between the offsets of the two halves of the LT1002. This error cancellation principle holds for a considerable number of input referred parameters in addition to offset voltage and its drift with temperature. Input bias current will be the average of the two non-inverting input currents (I_B^+). The difference between these two currents (I_{OS}^+) is the offset current of the instrumentation amplifier. The difference between the inverting input currents (I_{OS}^-) will cause errors flowing through R1, R2, and R3. Common-mode and power supply rejections will be dependent only on the match between the two amplifiers (assuming perfect resistor matching).

The concepts of common mode and power supply rejection ratio match ($\Delta CMRR$ and $\Delta PSRR$) are best demonstrated with a numerical example:

Assume $CMRR_A = +1.0\mu V/V$ or 120dB, and $CMRR_B = +0.75\mu V/V$ or 122.5dB, then $\Delta CMRR = 0.25\mu V/V$ or 132dB; if $CMRR_B = -0.75\mu V/V$ which is still 122.5dB, then $\Delta CMRR = 1.75\mu V/V$ or 115dB.

Clearly, the LT1002, by specifying and guaranteeing all of these matching parameters, can significantly improve the performance of matching dependent circuits.

Three Op Amp Instrumentation Amplifier

Trim R8 for gain

Trim R9 for DC common mode rejection

Trim R10 for AC common mode rejection

Typical performance of the instrumentation amplifier:

Input offset voltage = $25\mu V$

Input bias current = $0.7nA$

Input resistance = 200Ω

Input offset current = $0.6nA$

Input noise = $0.5\mu V$ p-p

Power bandwidth ($V_0 = \pm 10V$) = 80kHz

Precision $\pm 10V$ Reference

The LT1002 contributes less than 5% of the total drift with temperature, noise and long term drift of the ref-

erence. The accuracy of the $-10V$ output is limited by the matching of the two 10k resistors.

Dual Limit Microvolt Comparator

When the upper or lower limit is exceeded the LED lights up. Positive feedback to one of the nulling terminals creates 5 to 20 μV of hysteresis on both amplifiers. This feedback changes the offset voltage of the

LT1002 by less than 5 μV . Therefore, the basic accuracy of the comparator is limited only by the low offset voltage of the LT1002.

APPLICATIONS INFORMATION

Two Op Amp Instrumentation Amplifier

* TRIM FOR COMMON-MODE REJECTION

+ TRIM FOR GAIN

$$\text{Gain} = \frac{R_4}{R_3} \left[1 + \frac{1}{2} \left(\frac{R_2}{R_1} + \frac{R_3}{R_4} \right) + \frac{R_2 + R_3}{R_5} \right] \approx 100$$

Precision Amplifier Drives 500Ω Load to ±10V

This application utilizes the guaranteed 10mA load driving capability of the LT1002. The offset voltage of amplifier A is the offset of the configuration. Amplifier B provides the additional 10mA load current. When load resistor R_L is removed, amplifier A sinks this current without affecting accuracy. In the gain of 1000 configuration shown, approximately 0.3% gain accuracy can be realized.

- Microphone Preamplifiers

DESCRIPTION

The LT1007/LT1037 series features the lowest noise performance available to date for monolithic operational amplifiers: 2.5nV/√Hz wideband noise (less than the noise of a 400Ω resistor), 1/f corner frequency of 2Hz and 60nV peak to peak 0.1Hz to 10Hz noise. Low noise is combined with outstanding precision and speed specifications: 10μV offset voltage, 0.2μV/°C drift, 130 dB common-mode and power supply rejection, and 60MHz gain-bandwidth-product on the de-compensated LT1037, which is stable for closed loop gains of 5 or greater.

The voltage gain of the LT1007/1037 is an extremely high 20 million driving a 2kΩ load and 12 million driving a 600Ω load to ±10V.

In the design, processing, and testing of the device, particular attention has been paid to the optimization of the entire distribution of several key parameters. Consequently, the specifications of even the lowest cost grades (the LT1007C and the LT1037C) have been spectacularly improved compared to equivalent grades of competing amplifiers.

The sine wave generator application shown below utilizes the low noise and low distortion characteristics of the LT1037.

Ultra-Pure 1kHz Sine Wave Generator

Total Harmonic Distortion = < .0025%
 Noise = < .0001%
 Amplitude = ± 8 volts
 Output Frequency = 1.000kHz for values given ± .4%

0.1Hz to 10Hz Noise

ABSOLUTE MAXIMUM RATINGS

Supply Voltage $\pm 22\text{V}$
 Input Voltage Equal to Supply Voltage
 Output Short Circuit Duration Indefinite
 Differential Input Current (Note 8) $\pm 25\text{mA}$
 Lead Temperature (Soldering, 10 sec.) 300°C
 Operating Temperature Range

LT1007/1037AM, M -55°C to 125°C

LT1007/1037AC, C 0°C to 70°C

Storage Temperature Range

All Devices -65°C to 150°C

NOTES:

The ● denotes the specifications which apply over full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Input Offset Voltage measurements are performed by automatic test equipment approximately 0.5 seconds after application of power. AM and AC grades are guaranteed fully warmed up.

Note 2: Long Term Input Offset Voltage Stability refers to the average trend line of Offset Voltage vs. Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 days are typically $2.5\mu V$ — refer to typical performance curve.

Note 3: This parameter is tested on a sample basis only.

Note 4: 10Hz noise voltage density is sample tested on every lot. Devices 100% tested at 10Hz are available on request.

Note 5: See the test circuit and frequency response curve for 0.1Hz to 10Hz tester in the Applications Information section.

Note 6: See the test circuit for current noise measurement in the Applications Information section.

Note 7: This parameter is guaranteed by design and is not tested.

Note 8: The inputs are protected by back-to-back diodes. Current limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds $\pm 0.7V$, the input current should be limited to 25mA.

Note 9: The Average Input Offset Drift performance is within the specifications unnullled or when nulled with a pot having a range of $8k\Omega$ to $20k\Omega$.

APPLICATIONS INFORMATION

General

The LT1007/1037 series devices may be inserted directly into OP-07, OP-27, OP-37, and 5534 sockets with or without removal of external compensation or nulling components. In addition, the LT1007/1037 may be fitted to 741 sockets with the removal or modification of external nulling components.

Offset Voltage Adjustment

The input offset voltage of the LT1007/1037 and its drift with temperature, are permanently trimmed at wafer testing to a low level. However, if further adjustment of V_{OS} is necessary, the use of a 10k nulling potentiometer will not degrade drift with temperature. Trimming to a value other than zero creates a drift of $(V_{OS}/300) \mu V/^{\circ}C$, e.g., if V_{OS} is adjusted to $300 \mu V$, the change in drift will be $1 \mu V/^{\circ}C$.

Standard Adjustment

The adjustment range with a 10k pot is approximately $\pm 2.5mV$. If less adjustment range is needed, the sensitivity and resolution of the nulling can be improved by using a smaller pot in conjunction with fixed resistors. The example has an approximate null range of $\pm 200 \mu V$.

Improved Sensitivity Adjustment

Offset Voltage and Drift

Thermocouple effects, caused by temperature gradients across dissimilar metals at the contacts to the input terminals, can exceed the inherent drift of the

amplifier unless proper care is exercised. Air currents should be minimized, package leads should be short, the two input leads should be close together and maintained at the same temperature.

The circuit shown to measure offset voltage is also used as the burn-in configuration for the LT1007/1037, with the supply voltages increased to $\pm 20V$.

Test Circuit for Offset Voltage and Offset Voltage Drift with Temperature

Unity Gain Buffer Applications (LT1007 Only)

When $R_f \leq 100\Omega$ and the input is driven with a fast, large signal pulse ($> 1V$), the output waveform will look as shown in the pulsed operation diagram.

During the fast feedthrough-like portion of the output, the input protection diodes effectively short the output to the input and a current, limited only by the output short circuit protection, will be drawn by the signal generator. With $R \geq 500\Omega$, the output is capable of handling the current requirements ($I_L \leq 20mA$ at $10V$) and the amplifier stays in its active mode and a smooth transition will occur.

As with all operational amplifiers when $R_f > 2k\Omega$, a pole will be created with R_f and the amplifier's input capacitance, creating additional phase shift and reducing the phase margin. A small capacitor (20pF to 50pF) in parallel with R_f will eliminate this problem.

the total noise versus source resistance plot, where
 $\text{total noise} = [(\text{voltage noise})^2 + (\text{current noise} \times R_s)^2 + (\text{resistor noise})^2]^{1/2}$

Three regions can be identified as a function of source resistance:

- (i) $R_s \leq 400\Omega$. Voltage noise dominates
- (ii) $400\Omega \leq R_s \leq 50k\Omega$ at 1kHz } Resistor noise dominates
- $400\Omega \leq R_s \leq 8k\Omega$ at 10Hz }

- (iii) $R_s > 50k\Omega$ at 1kHz } Current noise dominates
- $R_s > 8k\Omega$ at 10Hz }

Clearly the LT1007/1037 should not be used in region (iii), where total system noise is at least six times higher than the voltage noise of the op amp, i.e., the low voltage noise specification is completely wasted.

TYPICAL APPLICATIONS

Gain 1000 Amplifier with 0.01% Accuracy, DC to 5Hz

The high gain and wide bandwidth of the LT1037 and (LT1007) is useful in low frequency high closed loop gain amplifier applications. A typical precision Op Amp may have an open loop gain of one million with 500kHz bandwidth. As the gain error plot shows, this device is capable of 0.1% amplifying accuracy up to 0.3Hz only. Even instrumentation range signals can vary at a faster rate. The LT1037's "gain precision — bandwidth product" is 200 times higher, as shown.

**Gain Error vs Frequency
Closed Loop Gain = 1000**

Microvolt Comparator with Hysteresis

Positive feedback to one of the nulling terminals creates approximately 5μV of hysteresis. Output can sink 16mA.

Input offset voltage is typically changed less than 5μV due to the feedback.

Precision Amplifier Drives 300Ω Load to ±10V

The addition of the LT1007 doubles the amplifier's output drive to ±33mA. Gain accuracy is 0.02%, slightly degraded compared to above because of self heating of the LT1037 under load.

TYPICAL APPLICATIONS

Phono Preamplifier

Tape Head Amplifier

Infra-Red Detector Preamplifier

Strain Gauge Signal Conditioner with Bridge Excitation

The LT1007 is capable of providing excitation current directly to bias the 350Ω bridge at 5V. With only 5V across the bridge (as opposed to the usual 10V) total power dissipation and bridge warm-up drift is reduced. The bridge output signal is halved, but the LT1007 can amplify the reduced signal accurately.

FEATURES

- **Guaranteed Bias Current**
25°C 100pA max.
-55°C to 125°C 600pA max.
- **Guaranteed Offset Voltage** 120μV max.
- **Guaranteed Drift** 1.5μV/°C max.
- **Low Noise, 0.1Hz to 10Hz** 0.5μVp-p
- **Guaranteed Low Supply Current** 600μA max.
- **Guaranteed CMRR** 114 dB min.
- **Guaranteed PSRR** 114 dB min.
- **Guaranteed Voltage Gain with 5mA load current**

APPLICATIONS

- Precision instrumentation
- Charge integrators
- Wide dynamic range logarithmic amplifiers
- Light meters
- Low frequency active filters
- Standard cell buffers
- Thermocouple amplifiers

DESCRIPTION

The LT1008 is a universal precision operational amplifier which can be used in practically all precision applications. The LT1008 combines for the first time picoampere bias currents (which are maintained over the full -55°C to 125°C temperature range) microvolt offset voltage (and low drift with time and temperature), low voltage and current noise, and low power dissipation. Extremely high common-mode and power supply rejection ratios, and the ability to deliver 5mA load current with high voltage gain round out the LT1008's superb precision specifications.

The all around excellence of the LT1008 eliminates the necessity of the time consuming error analysis procedure of precision system design in many applications; the LT1008 can be stocked as the universal precision op amp.

The LT1008 is externally compensated with a single capacitor for additional flexibility in shaping the frequency response of the amplifier. It plugs into and upgrades all standard LM108A/308A applications. For an internally compensated version with even lower offset voltage but otherwise similar performance see the LT1012.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Differential input voltages greater than 1V will cause excessive current to flow through the input protection diodes unless current limiting resistors are used.

Note 2: These specifications apply for $\pm 2V \leq V_S \leq \pm 20V$ ($\pm 2.5V \leq V_S \leq \pm 20V$ over the temperature range) and $-13.5V \leq V_{CM} \leq 13.5V$ (for $V_S = \pm 15V$).

Note 3: 10Hz noise voltage density is sample tested on every lot. Devices 100% tested at 10Hz are available on request.

Note 4: This parameter is tested on a sample basis only.

$A_V = +1$, $C_S = 100\text{pF}$, $C_{LOAD} = 100\text{pF}$, $5\mu\text{sec/DIV}$

Small Signal Transient Response

$A_V = +1$, $C_S = 100\text{pF}$, $C_{LOAD} = 600\text{pF}$, $5\mu\text{sec/DIV}$

Small Signal Transient Response

$A_V = +1$, $C_f = 30\text{pF}$, $C_{LOAD} = 100\text{pF}$, $5\mu\text{sec/DIV}$

APPLICATIONS INFORMATION

Achieving Picoampere/Microvolt Performance

In order to realize the picoampere — microvolt level accuracy of the LT1008, proper care must be exercised. For example, leakage currents in circuitry external to the op amp can significantly degrade performance. High quality insulation should be used (e.g. Teflon, Kel-F); cleaning of all insulating surfaces to remove fluxes and other residues will probably be required. Surface coating may be necessary to provide a moisture barrier in high humidity environments.

Board leakage can be minimized by encircling the input circuitry with a guard ring operated at a potential close to that of the inputs: in inverting configurations the guard ring should be tied to ground, in non-invert-

ing connections to the inverting input at pin 2. Guarding both sides of the printed circuit board is required. Bulk leakage reduction depends on the guard ring width. Nanoampere level leakage into the compensation terminals can affect offset voltage and drift with temperature.

APPLICATIONS INFORMATION

Microvolt level error voltages can also be generated in the external circuitry. Thermocouple effects caused by temperature gradients across dissimilar metals at the contacts to the input terminals can exceed the inherent drift of the amplifier. Air currents over device leads should be minimized, package leads should be short, and the two input leads should be as close together as possible and maintained at the same temperature.

The LT1008 is specified over a wide range of power-supply voltages from $\pm 2\text{V}$ to $\pm 18\text{V}$. Operation with lower supplies is possible down to $\pm 1.0\text{V}$ (two Ni-Cad-batteries).

Test Circuit for Offset Voltage and its Drift with Temperature

Noise Testing

The 0.1Hz to 10Hz peak-to-peak noise of the LT1008 is measured in the test circuit shown. The frequency response of this noise tester indicates that the 0.1Hz corner is defined by only one zero. The test time to measure 0.1Hz to 10Hz noise should not exceed 10 seconds, as this time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1Hz.

A noise-voltage density test is recommended when measuring noise on a large number of units. A 10Hz noise-voltage density measurement will correlate well with a 0.1Hz to 10Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the 1/f corner frequency.

Current noise is measured in the circuit shown and calculated by the following formula where the noise of the source resistors is subtracted.

0.1Hz to 10Hz Noise Test Circuit

$$i_n = \frac{[e_{no}^2 - (820\text{nV})^2]^{1/2}}{40\text{M}\Omega \times 100}$$

APPLICATIONS INFORMATION

Frequency Compensation

The LT1008 is externally frequency compensated with a single capacitor. The two standard compensation circuits shown on page 3 are identical to the LM108A/308A frequency compensation schemes. Therefore, the LT1008 operational amplifiers can be inserted directly into LM108A/308A sockets, with similar AC and upgraded DC performance.

External frequency compensation provides the user with additional flexibility in shaping the frequency response of the amplifier. For example, for a voltage gain of ten, and $C_f = 3\text{pF}$, a gain bandwidth product of 5MHz and slew rate of $1.2\text{V}/\mu\text{sec}$ can be realized. For closed loop gains in excess of 200, no external compensation is necessary, and slew rate increases to $4\text{V}/\mu\text{sec}$. The LT1008 can also be overcompensated (i.e. $C_f > 30\text{pF}$ or $C_s > 100\text{pF}$) to improve capacitive load handling capability or to narrow noise band-

width. In many applications, the feedback loop around the amplifier has gain (e.g. logarithmic amplifiers); overcompensation can stabilize these circuits with a single capacitor.

The availability of the compensation terminals permits the use of feedforward frequency compensation to enhance slew rate in low closed loop gain configurations. The inverter slew rate is increased to $1.4\text{V}/\mu\text{sec}$. The voltage follower feedforward scheme bypasses the amplifier's gain stages and slews at nearly $10\text{V}/\mu\text{sec}$.

The inputs of the LT1008 are protected with back-to-back diodes. Current limiting resistors are not used, because the leakage of these resistors would prevent the realization of picoampere level bias currents at elevated temperatures. In the voltage follower configuration, when the input is driven by a fast, large signal pulse ($> 1\text{V}$), the input protection diodes effectively short the output to the input during slewing, and a current, limited only by the output short circuit protection will flow through the diodes.

The use of a feedback resistor, as shown in the voltage follower, feedforward diagram, is recommended because this resistor keeps the current below the short circuit limit, resulting in faster recovery and settling of the output.

APPLICATIONS

Logarithmic Amplifier

Amplifier for Bridge Transducers

Saturated Standard Cell Amplifier

The typical 30pA bias current of the LT1008 will degrade the standard cell by only 1 ppm/year. Noise is a fraction of a ppm. Unprotected gate MOSFET isolates standard cell on power down.

Amplifier For Photodiode Sensor

Five Decade Kelvin-Varley Divider Buffered by the LT1008

Approximate error due to noise, bias current, common-mode rejection, voltage gain of the amplifier is 1/5 of a least significant bit.

Extended Range Charge Pump Voltage to Frequency Converter

The LT1008 integrator extends low frequency range. Total dynamic range is 0.01Hz to 10kHz (or 120dB) with 0.01% linearity.

Precision, Fast Settling, Low Pass Filter

This circuit is useful where fast signal acquisition and high precision are required, as in electronic scales.

The filter's time constant is set by the $2K\Omega$ resistor and the $1\mu F$ capacitor until comparator #1 switches. The time constant is then set by the $1.5M\Omega$ resistor and the $1\mu F$ capacitor. Comparator #2 provides a quick reset.

The circuit settles to a final value three times as fast as a simple $1.5\text{M}\Omega - 1\mu\text{F}$ filter, with almost no DC error.

The circuit diagram shows two operational amplifier ICs: LT318A and LT1008. The LT318A is configured as a precision half-wave rectifier. Its non-inverting input (pin 3) is connected to the input signal through a 10k resistor. The inverting input (pin 2) is connected to the output of the LT1008 through a 15k resistor. The output of the LT318A (pin 6) is connected to the output of the LT1008 (pin 6) through a 10k resistor. The LT1008 is configured as a precision full-wave rectifier. Its non-inverting input (pin 3) is connected to ground through a 10k resistor. The inverting input (pin 2) is connected to the input signal through a 10k resistor. The output of the LT1008 (pin 6) is connected to the output of the LT318A through a 10k resistor. The LT1008 also has a feedback capacitor of 300pF connected between its output (pin 6) and its inverting input (pin 2). The LT318A has a feedback capacitor of 2T0 8pF connected between its output (pin 6) and its inverting input (pin 2). The circuit is powered by a +15V supply and a -15V supply. The input is labeled 'INPUT' and the output is labeled 'OUTPUT'.

The circuit diagram shows an LT1008 operational amplifier configured as a current source. The non-inverting input (pin 3) is connected to ground. The inverting input (pin 2) is connected to a 'CURRENT INPUT' through a 10k resistor. The output (pin 6) is connected to a 33k resistor, which is in turn connected to the base of a PNP transistor Q1. The emitter of Q1 is connected to ground. The collector of Q1 is connected to the base of an NPN transistor Q2. The emitter of Q2 is connected to ground. The collector of Q2 is connected to a 'RANGE' terminal, which is also connected to a 100μA METER. The 'RANGE' terminal is connected to a decade resistor array (LT1004C-1.2) through a 100pA terminal. The array consists of resistors with values 100pA, 1nA, 10nA, 100nA, 1μA, 10μA, and 100μA. The other end of the array is connected to a +15V supply through a 10k resistor. The op-amp is powered by a +15V supply (pin 7) and a -15V supply (pin 4). A 0.01μF capacitor is connected between pins 1 and 8. Pin 13 is connected to ground and is labeled 'PIN 13 CA 3146'. The text '46 TRANSISTOR ARRAY. FOR FULL SCALE PUT CURRENT.' is visible in the background.

Q1, Q2, Q3, Q4, RCA CA3146 TRANSISTOR ARRAY.
CALIBRATION: ADJUST R1 FOR FULL SCALE
DEFLECTION WITH $1\mu\text{A}$ INPUT CURRENT.

Ammeter measures currents from 100pA to 100μA without the use of expensive high value resistors. Accuracy at 100μA is limited by the offset voltage between Q1 and Q2 and, at 100pA, by the inverting bias current of the LT1008.

FEATURES

- 20MHz Bandwidth
- 75V/ μs Slew Rate
- Drives $\pm 10\text{V}$ into 75 Ω
- 5mA Quiescent Current
- Drives Capacitive Loads $> 1\mu\text{F}$
- Current and Thermal Limit
- Operates from Single Supply $\geq 4.5\text{V}$

APPLICATIONS

- Boost Op Amp Output
- Isolate Capacitive Loads
- Drive Long Cables
- Video Amplifiers
- Power Small Motors
- Operate Proportional Actuators
- Operational Power Supply

DESCRIPTION

The LT1010 is a fast, unity-gain buffer that can increase the output capability of existing IC op amps by more than an order of magnitude. This easy-to-use part makes fast amplifiers less sensitive to capacitive loading, reduces thermal feedback in precision dc amplifiers and is recommended for a wide range of fast and slow applications.

Designed to be incorporated within the feedback loop, the buffer can isolate almost any reactive load. Internal operating currents are essentially unaffected by supply or output voltage, accounting for the 4.5V to 40V supply voltage range with unchanged specifications. Single-supply operation is also practical.

This monolithic IC is supplied in three standard power packages: the solid kovar base TO-5 (TO-39), the steel TO-3 and the plastic TO-220. These low thermal resistance packages are an aid in reducing operating junction temperatures. With the TO-3 and TO-220 packages, an option is available to raise quiescent current and improve speed.

In the TO-39 package, the LT1010 can sometimes replace the hybrid LH0002. With the exception of speed it exceeds key specifications and fault protection is vastly better. Further, the lower thermal resistance package and higher maximum operating temperature of the new monolithic circuit allow more usable output.

			•		9		10	mA

Note 1: For case temperatures above 25°C, dissipation must be derated based on a thermal resistance of 25°C/W with the K and T packages or 40°C/W with the H package. See applications information.

Note 2: In current limit or thermal limit, input current increases sharply with input-output differentials greater than 8V; so input current must be limited. Input current also rises rapidly for input voltages 8V above V^+ or 0.5V below V^- .

Note 3: Specifications apply for $4.5V \leq V_S \leq 40V$, $V^- + 0.5V \leq V_{IN} \leq V^+ - 1.5V$ and $I_{OUT} = 0$, unless otherwise stated. Temperature range is $-55^\circ C \leq T_J \leq 150^\circ C$, $T_C \leq 125^\circ C$, for the LT1010M and $0^\circ C \leq T_J \leq 125^\circ C$, $T_C \leq 100^\circ C$, for the LT1010C. The ● denotes the specifications that apply over the full temperature range.

Note 4: The output saturation characteristics are measured with 100mV output clipping. See applications information for determining available output swing and input drive requirements for a given load.

Note 5: With the TO-3 and TO-220 packages, output stage quiescent current can be increased by connecting a resistor between the bias pin and V^+ . The increase is equal to the bias terminal voltage divided by this resistance.

APPLICATIONS INFORMATION

General

These notes briefly describe the LT1010 and how it is used; a detailed explanation is given elsewhere.* Emphasis here will be on practical suggestions that have resulted from working extensively with the part over a wide range of conditions. A number of applications are also outlined that demonstrate the usefulness of the buffer beyond that of driving a heavy load.

Design Concept

The schematic below describes the basic elements of the buffer design. The op amp drives the output sink transistor, Q3, such that the collector current of the output follower, Q2, never drops below the quiescent value (determined by I_1 and the area ratio of D1 and D2). As a result, the high frequency response is essentially that of a simple follower even when Q3 is supplying the load current. The internal feedback loop is isolated from the effects of capacitive loading by a small resistor in the output lead.

The scheme is not perfect in that the rate of rise of sink current is noticeably less than for source current. This can be mitigated by connecting a resistor between the bias terminal and V^+ , raising quiescent current. A feature of the final design is that the output resistance is largely independent of the follower quiescent current or the output load current. The output will also swing to the negative rail, which is particularly useful with single-supply operation.

*R. J. Widlar, "Unique IC Buffer Enhances Op Amp Designs; Tames Fast Amplifiers", *Linear Technology Corp. TP-1*, April, 1984.

Equivalent Circuit

Below 1MHz, the LT1010 is quite accurately represented by the equivalent circuit shown here for both small and large signal operation. The internal element, A1, is an idealized buffer with the unloaded gain specified for the LT1010. Otherwise, it has zero offset voltage, bias current and output resistance. Its output also saturates to the internal supply terminals.[†]

Loaded voltage gain can be determined from the unloaded gain, A_v , the output resistance, R_{OUT} , and the load resistance, R_L , using

$$A_{VL} = \frac{A_v R_L}{R_{OUT} + R_L}$$

Maximum positive output swing is given by

$$V_{OUT}^+ = \frac{(V^+ - V_{SOS}^+) R_L}{R_{SAT} + R_L}$$

The input swing required for this output is

$$V_{IN}^+ = V_{OUT}^+ \left(1 + \frac{R_{OUT}}{R_L} \right) - V_{OS} + \Delta V_{OS},$$

where ΔV_{OS} is the 100mV clipping specified for the saturation measurements. Negative output swing and input drive requirements are similarly determined.

† See electrical characteristics section for guaranteed limits.

APPLICATIONS INFORMATION

Supply Bypass

The buffer is no more sensitive to supply bypassing than slower op amps, as far as stability is concerned. The $0.1\mu\text{F}$ disc ceramic capacitors usually recommended for op amps are certainly adequate for low frequency work. As always, keeping the capacitor leads short and using a ground plane is prudent, especially when operating at high frequencies.

The buffer slew rate can be reduced by inadequate supply bypass. With output current changes much above $100\text{mA}/\mu\text{s}$, using $10\mu\text{F}$ solid tantalum capacitors on both supplies is good practice, although bypassing from the positive to the negative supply may suffice.

When used in conjunction with an op amp and heavily loaded (resistive or capacitive), the buffer can couple into supply leads common to the op amp causing stability problems with the overall loop and extended settling time. Adequate bypassing can usually be provided by $10\mu\text{F}$ solid tantalum capacitors. Alternately, smaller capacitors could be used with decoupling resistors. Sometimes the op amp has much better high frequency rejection on one supply, so bypass requirements are less on this supply.

Power Dissipation

In many applications, the LT1010 will require heat sinking. Thermal resistance, junction to still air is $150^\circ\text{C}/\text{W}$ for the TO-39 package, $100^\circ\text{C}/\text{W}$ for the TO-220 package and $60^\circ\text{C}/\text{W}$ for the TO-3 package. Circulating air, a heat sink or mounting the package to a printed circuit board will reduce thermal resistance.

In dc circuits, buffer dissipation is easily computed. In ac circuits, signal waveshape and the nature of the load determine dissipation. Peak dissipation can be several

times average with reactive loads. It is particularly important to determine dissipation when driving large load capacitance.

With ac loading, power is divided between the two output transistors. This reduces the effective thermal resistance, junction to case, to $30^\circ\text{C}/\text{W}$ for the TO-39 package and $15^\circ\text{C}/\text{W}$ for the TO-3 and TO-220 packages, as long as the peak rating of neither output transistor is exceeded. The typical curves indicate the peak dissipation capabilities of one output transistor.

Overload Protection

The LT1010 has both instantaneous current limit and thermal overload protection. Foldback current limiting has not been used, enabling the buffer to drive complex loads without limiting. Because of this, it is capable of power dissipation in excess of its continuous ratings.

Normally, thermal overload protection will limit dissipation and prevent damage. However, with more than 30V across the conducting output transistor, thermal limiting is not quick enough to insure protection in current limit. The thermal protection is effective with 40V across the conducting output transistor as long as the load current is otherwise limited to 150mA.

Drive Impedance

When driving capacitive loads, the LT1010 likes to be driven from a low source impedance at high frequencies. Certain low power op amps (e.g., the LM10) are marginal in this respect. Some care may be required to avoid oscillations, especially at low temperatures.

Bypassing the buffer input with more than 200pF will solve the problem. Raising the operating current also works, but this cannot be done with the TO-39 package.

APPLICATIONS INFORMATION

Parallel Operation

Parallel operation provides reduced output impedance, more drive capability and increased frequency response under load. Any number of buffers can be directly paralleled as long as the increased dissipation in individual units caused by mismatches of output resistance and offset voltage is taken into account.

When the inputs and outputs of two buffers are connected together, a current, ΔI_{OUT} , flows between the outputs:

$$\Delta I_{OUT} = \frac{V_{OS1} - V_{OS2}}{R_{OUT1} + R_{OUT2}}$$

where V_{OS} and R_{OUT} are the offset voltage and output resistance of the respective buffers.

Normally, the negative supply current of one unit will increase and the other decrease, with the positive supply current staying the same. The worst-case ($V_{IN} \rightarrow V^+$) increase in standby dissipation can be assumed to be $\Delta I_{OUT} V_T$, where V_T is the total supply voltage.

Offset voltage is specified worst-case over a range of supply voltages, input voltage and temperature. It would be unrealistic to use these worst-case numbers above because paralleled units are operating under identical conditions. The offset voltage specified for $V_S = \pm 15V$, $V_{IN} = 0$ and $T_A = 25^\circ C$ will suffice for a worst-case condition.

Output load current will be divided based on the output resistance of the individual buffers. Therefore, the available output current will not quite be doubled unless output resistances are matched. As for offset voltage above, the $25^\circ C$ limits should be used for worst-case calculations.

Parallel operation is not thermally unstable. Should one unit get hotter than its mates, its share of the output and its standby dissipation will decrease.

As a practical matter, parallel connection needs only some increased attention to heat sinking. In some applications, a few ohms equalization resistance in each output may be wise. Only the most demanding applications should require matching, and then just of output resistance at $25^\circ C$.

Isolating Capacitive Loads

The inverting amplifier above shows the recommended method of isolating capacitive loads. Non-inverting amplifiers are handled similarly.

At lower frequencies, the buffer is within the feedback loop so that its offset voltage and gain errors are negligible. At higher frequencies, feedback is through C_F , so that phase shift from the load capacitance acting against the buffer output resistance does not cause loop instability.

Stability depends upon the $R_F C_F$ time constant, or the closed loop bandwidth. With an 80kHz bandwidth, ringing is negligible for $C_L = 0.05\mu F$ and damps rapidly for $C_L = 0.3\mu F$.

APPLICATIONS INFORMATION

Small signal bandwidth is reduced by C_f , but considerable isolation can be obtained without reducing it below the power bandwidth. Often, a bandwidth reduction is desirable to filter high frequency noise or unwanted signals.

The follower configuration is unique in that capacitive load isolation is obtained without a reduction in small signal bandwidth, although the output impedance of the buffer comes into play at high frequencies. The precision unity-gain buffer above has a 10MHz bandwidth without capacitive loading, yet it is stable for all load capacitance to over $0.3\mu F$, again determined by $R_f C_f$.

This is a good example of how fast op amps can be made quite easy to use by employing an output buffer.

Integrator

A low pass amplifier can be formed just by using large C_f in the inverter described earlier, as long as the increasing closed loop output impedance above the cutoff frequency is not a problem and the op amp is capable of supplying the required current at the summing junction.

If the integrating capacitor must be driven from the buffer output, the circuit above can be used to provide capacitive load isolation. As before, the stability with large capacitive loads is determined by $R_f C_f$.

Wideband Amplifiers

This simple circuit provides an adjustable gain video amplifier which will drive 1V p-p into 75Ω . The differential pair provides gain, with the LT1010 serving as an output stage. Feedback is arranged in the conventional manner, although the $68\mu F - 0.01$ combination limits DC gain to unity for all gain settings. For applications sensitive to NTSC requirements, dropping the 25Ω output stage bias value will aid performance.

APPLICATIONS INFORMATION

This shows the buffer being used with a wideband amplifier that is not unity-gain stable. In this case, C1 cannot be used to isolate large capacitive loads. Instead, it has an optimum value for a limited range of load capacitances.

The buffer can cause stability problems in circuits like this. With the TO-3 and TO-220 packages, behavior can be improved by raising the quiescent current with a 20 Ω resistor from the bias terminal to V^+ . Alternately, devices in the TO-39 package can be operated in parallel.

It is possible to improve capacitive load stability by operating the buffer class-A at high frequencies. This is done by using quiescent current boost and bypassing the bias terminal to V^- with more than 0.02 μ F.

Putting the buffer outside the feedback loop as shown here will give capacitive load isolation, with large output

capacitors only reducing bandwidth. Buffer offset, referred to the op amp input, is divided by the gain. If the load resistance is known, gain error is determined by the output resistance tolerance. Distortion is low.

The 50 Ω video line splitter shown here puts feedback on one buffer, with the others slaved. Offset and gain accuracy of slaves depend on their matching with master.

When driving long cables, including a resistor in series with the output should be considered. Although it reduces gain, it does isolate the feedback amplifier from the effects of unterminated lines which present a resonant load.

When working with wideband amplifiers, special attention should *always* be paid to supply bypassing, stray capacitance and keeping leads short. Direct grounding of test probes, rather than the usual ground lead, is absolutely necessary for reasonable results.

The LT1010 has slew limitations that are not obvious from standard specifications. Negative slew is subject to glitching, but this can be minimized with quiescent current boost. The appearance is always worse with fast rise signal generators than in practical applications.

APPLICATIONS INFORMATION

Track and Hold

The 5MHz track and hold shown here has a 400kHz power bandwidth driving $\pm 10\text{V}$. A buffered input follower drives the hold capacitor, C4, through Q1, a low resistance FET switch. The positive hold command is supplied by TTL logic, with Q3 level shifting to the switch driver, Q2. The output is buffered by A3.

When the gate is driven to V^- for HOLD, it pulls charge out of the hold capacitor. A compensating charge is put into the hold capacitor through C3. The step into hold is made independent of the input level with R7 and adjusted to zero with R10.

Since internal dissipation can be quite high when driving fast signals into a capacitive load, using a buffer in a power package is recommended. Raising buffer quiescent current to 40mA with R3 improves frequency response.

This circuit is equally useful as a fast acquisition sample and hold. An LF156 might be used for A3 to reduce drift in hold because its lower slew rate is not usually a problem in this application.

*2N2369 EMITTER BASE JUNCTION

APPLICATIONS INFORMATION

Current Sources

A standard op amp voltage to current converter with a buffer to increase output current is shown here. As usual, excellent matching of the feedback resistors is required to get high output resistance. Output is bi-directional.

This circuit uses an instrumentation amplifier to eliminate the matched resistors. The input is not high impedance and must be driven from a low impedance source like an op amp. Reversal of output sense can be obtained by grounding pin 7 of the LM163 and driving pin 5.

Output resistances of several megohms can be obtained with both circuits. This is impressive considering the $\pm 150\text{mA}$ output capability. High frequency output characteristics will depend on the bandwidth and slew rate of the amplifiers. Both these circuits have an equivalent output capacitance of about 30nF.

Voltage Regulator

Although it operates from a single supply, this circuit will regulate voltage down to 200mV. It will also source or sink current.

The ability of the circuit to handle capacitive loads is determined by R3 and C1. The values given are optimized for up to 1 μF output capacitance, as might be required for an IC test supply.

The purpose of C1 is to lower the drive impedance to the buffer as discussed earlier. It is, incidentally, important to connect pin 4 of the LM10 and the bottom of R2 to a common ground point to avoid ground loop problems.

Voltage / Current Regulator

APPLICATIONS INFORMATION

This circuit regulates the output voltage at V_Y until the load current reaches a value programmed by V_I . For heavier loads, it is a precision current regulator.

With output currents below the current limit, the current regulator is disconnected from the loop by D1, with D2 keeping its output out of saturation. This output clamp enables the current regulator to get control of the output current from the buffer current limit within a microsecond for an instantaneous short.

In the voltage regulation mode, A1 and A2 act as a fast voltage follower using the capacitive load isolation technique described earlier. Load transient recovery as well as capacitive load stability are determined by C1. Recovery from short circuit is clean.

Bi-directional current limit can be obtained by adding another op amp connected as a complement to A3.

Supply Splitter

Dual supply op amps and comparators can be operated from a single supply by creating an artificial ground at half the supply voltage. The supply splitter shown here can source or sink 150mA.

The output capacitor, C2, can be made as large as necessary to absorb current transients. An input capacitor is also used on the buffer to avoid high frequency instability that can be caused by high source impedance.

Overload Clamping

The input of a summing amplifier is at virtual ground as long as it is in the active region. With overloads, this is no longer true, unless the feedback is kept active.

This schematic shows a chopper stabilized current to voltage converter. It is capable of 10pA resolution, yet is able to keep the summing node under control with overload currents to $\pm 150\text{mA}$.

During normal operation, D3 and D4 are not conducting; and R1 absorbs any leakage current from the zener clamps, D6 and D7. In overload, current is supplied to the summing node through the zener clamps, rather than the scaling resistor, R2.

DEFINITION OF TERMS

Output Offset Voltage: The output voltage measured with reference to the input.

Input Bias Current: The current out of the input terminal.

Large Signal Voltage Gain: The ratio of the output voltage change to the input voltage change over the specified input voltage range.*

Output Resistance: The ratio of the change in output voltage to the change in load current producing it.*

Output Saturation Voltage: The voltage between the output and the supply rail at the limit of the output swing toward that rail.

Saturation Offset Voltage: The output saturation voltage with no load.

Saturation Resistance: The ratio of the change in output saturation voltage to the change in current producing it, going from no load to full load.*

Slew Rate: The average time rate of change of output voltage over the specified output range with an input step between the specified limits.

Bias Terminal Voltage: The voltage between the bias terminal and V^+ .

Supply Current: The current at either supply terminal with no output loading.

*Pulse measurements ($\sim 1\text{ms}$) as required to minimize thermal effects.

DEFINITION OF TERMS

Output Offset Voltage: The output voltage with no load and no input signal, referred to the output.

Input Bias Current: The current flowing into or out of the input terminals.

Load Regulator Voltage Gain: The ratio of the change in output voltage to the change in input voltage over the specified input voltage range.

Output Resistance: The ratio of the change in output voltage to the change in load current with the input voltage held constant.

Regulator Saturation Voltage: The output voltage when the output current is at its maximum value and the supply voltage is held constant.

Saturated Output Current: The output current when the output voltage is at its minimum value and the supply voltage is held constant.

Picoamp Input Current,
Microvolt Offset,
Low Noise Op Amp

FEATURES

- Internally Compensated
- Guaranteed Offset Voltage $35\mu\text{V}$ max.
- Guaranteed Bias Current 100pA max.
- 25°C 600pA max.
- -55°C to 125°C $1.5\mu\text{V}/^\circ\text{C}$ max.
- Guaranteed Drift $0.5\text{mV}/^\circ\text{C}$ max.
- 0.1Hz to 10Hz 0.5mVp-p
- Guaranteed Low Supply Current $600\mu\text{A}$ max.
- Guaranteed CMRR 114dB min.
- Guaranteed PSRR 114dB min.
- Guaranteed Voltage Gain with 5mA load current

APPLICATIONS

- Precision instrumentation
- Charge integrators
- Wide dynamic range logarithmic amplifiers
- Light meters
- Low frequency active filters
- Standard cell buffers
- Thermocouple amplifiers

DESCRIPTION

The LT1012 is an internally compensated universal precision operational amplifier which can be used in practically all precision applications. The LT1012 combines picoampere bias currents (which are maintained over the full -55°C to 125°C temperature range), microvolt offset voltage (and low drift with time and temperature), low voltage and current noise, and low power dissipation. Extremely high common-mode and power supply rejection ratios, practically unmeasurable warm-up drift, and the ability to deliver 5mA load current with a voltage gain of a million round out the LT1012's superb precision specifications.

The all around excellence of the LT1012 eliminates the necessity of the time consuming error analysis procedure of precision system design in many applications; the LT1012 can be stocked as the universal internally compensated precision op amp.

For an externally compensated version with additional flexibility in shaping the frequency response of the amplifier, but otherwise similar performance, see the LT1008.

Kelvin-Sensed Platinum Temperature Sensor Amplifier

Positive feedback (R_1) linearizes the inherent parabolic nonlinearity of the platinum sensor and reduces errors from 1.2°C to 0.004°C over the -50°C to 150°C range.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Differential input voltages greater than 1V will cause excessive current to flow through the input protection diodes unless limiting resistance is used.

Note 2: These specifications apply for $\pm 2V \leq V_S \leq \pm 20V$ ($\pm 2.5V \leq V_S \leq \pm 20V$ over the temperature range) and $-13.5V \leq V_{CM} \leq 13.5V$ (for $V_S = \pm 15V$).

Note 3: 10Hz noise voltage density is sample tested on every lot. Devices 100% tested at 10Hz are available on request.

Note 4: This parameter is tested on a sample basis only.

Optional Offset Nulling and Over-Compensation Circuits

Input offset voltage can be adjusted over a $\pm 800\mu V$ range with a 5k to 100k potentiometer.

The LT1012 is internally compensated for unity gain stability. The over-compensation capacitor, C_S , can be used to improve capacitive load handling capability, to narrow noise bandwidth, or to stabilize circuits with gain in the feedback loop.

APPLICATIONS INFORMATION

The LT1012 may be inserted directly into OP-07, LM11, 108A or 101A sockets with or without removal of external frequency compensation or nulling components. The LT1012 can also be used in 741, LF411, LF156 or OP-15 applications provided that the nulling circuitry is removed.

The LT1012 is specified over a wide range of power supply voltages from $\pm 2V$ to $\pm 18V$. Operation with lower supplies is possible down to $\pm 1.0V$ (two Ni-Cad batteries).

Achieving Picoampere/Microvolt Performance

In order to realize the picoampere — microvolt level accuracy of the LT1012, proper care must be exercised. For example, leakage currents in circuitry exter-

nal to the op amp can significantly degrade performance. High quality insulation should be used (e.g. Teflon, Kel-F); cleaning of all insulating surfaces to remove fluxes and other residues will probably be required. Surface coating may be necessary to provide a moisture barrier in high humidity environments.

APPLICATIONS INFORMATION

Board leakage can be minimized by encircling the input circuitry with a guard ring operated at a potential close to that of the inputs: in inverting configurations the guard ring should be tied to ground, in non-inverting connections to the inverting input at pin 2. Guarding both sides of the printed circuit board is required. Bulk leakage reduction depends on the guard ring width. Nanoampere level leakage into the offset trim terminals can affect offset voltage and drift with temperature.

Microvolt level error voltages can also be generated in the external circuitry. Thermocouple effects caused by temperature gradients across dissimilar metals at the contacts to the input terminals can exceed the inherent drift of the amplifier. Air currents over device leads should be minimized, package leads should be short, and the two input leads should be as close together as possible and maintained at the same temperature.

Noise Testing

For application information on noise testing and calculations, please see the LT1008 data sheet.

Frequency Compensation

The LT1012 can be overcompensated to improve capacitive load handling capability or to narrow noise bandwidth. In many applications, the feedback loop around the amplifier has gain (e.g. logarithmic amplifiers); overcompensation can stabilize these circuits with a single capacitor.

The availability of the compensation terminal permits the use of feedforward frequency compensation to enhance slew rate. The voltage follower feedforward scheme bypasses the amplifier's gain stages and slews at nearly $10\text{V}/\mu\text{sec}$.

The inputs of the LT1012 are protected with back-to-back diodes. Current limiting resistors are not used, because the leakage of these resistors would prevent the realization of picoampere level bias currents at elevated temperatures. In the voltage follower configura-

tion, when the input is driven by a fast, large signal pulse ($> 1\text{V}$), the input protection diodes effectively short the output to the input during slewing, and a current, limited only by the output short circuit protection will flow through the diodes.

The use of a feedback resistor, as shown in the voltage follower feedforward diagram, is recommended because this resistor keeps the current below the short circuit limit, resulting in faster recovery and settling of the output.

Follower Feedforward Compensation

Pulse Response of Feedforward Compensation

TYPICAL APPLICATIONS

Resistor Multiplier

"No Trims" 12 bit Multiplying DAC Output Amplifier

When the reference input drops to 0.1V, the least significant bit decreases to the microvolt/picoampere range.

Low Power Comparator with <10μV Hysteresis

Instrumentation Amplifier with ±100 Volt Common Mode Range

Input Amplifier for 4½ Digit Voltmeter

Air Flow Detector

Mount R_1 in airflow.
Adjust R_2 so output goes high when airflow stops.

FN507
ALLEN BRADLEY
DECADE VOLTAGE DIVIDER

This application requires low bias current and offset voltage, low noise, and low drift with time and temperature.

TYPICAL APPLICATIONS

Logarithmic Amplifier

Saturated Standard Cell Amplifier

The typical 30pA bias current of the LT1012 will degrade the standard cell by only 1 ppm/year. Noise is a fraction of a ppm. Unprotected gate MOSFET isolates standard cell on power down.

Amplifier for Bridge Transducers

Amplifier For Photodiode Sensor

Buffered Reference for A to D Converters

TYPICAL APPLICATIONS

1Hz to 1MHz Voltage to Frequency Converter

All diodes: 1N4148

The LT1012 provides DC stabilization for the 356 integrator, allowing 120dB dynamic range. No offset trim is required.

Quad Precision Op Amp (LT1014) Dual Precision Op Amp (LT1013)

FEATURES

- Single Supply Operation
 - Input Voltage Range Extends to Ground
 - Output Swings to Ground while Sinking Current
- Pin Compatible to 1458 and 324 with Precision Specs
- Guaranteed Offset Voltage 150 μ V Max.
- Guaranteed Low Drift 2 μ V/ $^{\circ}$ C Max.
- Guaranteed Offset Current 0.8nA Max.
- Guaranteed High Gain
 - 5mA Load Current 1.5 Million Min.
 - 17mA Load Current 0.8 Million Min.
- Guaranteed Low Supply Current 500 μ A Max.
- Low Voltage Noise, 0.1Hz to 10Hz 0.55 μ Vp-p
- Low Current Noise—Better than OP-07, 0.07 pA/ $\sqrt$ Hz

APPLICATIONS

- Battery-Powered Precision Instrumentation
 - Strain Gauge Signal Conditioners
 - Thermocouple Amplifiers
 - Instrumentation Amplifiers
- 4mA–20mA Current Loop Transmitters
- Multiple Limit Threshold Detection
- Active Filters
- Multiple Gain Blocks

DESCRIPTION

The LT1014 is the first precision quad operational amplifier which directly upgrades designs in the industry standard 14-pin DIP LM324/LM348/OP-11/4156 pin configuration. It is no longer necessary to compromise specifications, while saving board space and cost, as compared to single operational amplifiers.

The LT1014's low offset voltage of 50 μ V, drift of 0.3 μ V/ $^{\circ}$ C, offset current of 0.15nA, gain of 8 million, common-mode rejection of 117dB, and power supply rejection of 120dB qualify it as four truly precision operational amplifiers. Particularly important is the low offset voltage, since no offset null terminals are provided in the quad configuration. Although supply current is only 350 μ A per amplifier, a new output stage design sources and sinks in excess of 20mA of load current, while retaining high voltage gain.

Similarly, the LT1013 is the first precision dual op amp in the 8-pin industry standard configuration, upgrading the performance of such popular devices as the MC1458/1558, LM158 and OP-221. The LT1013's specifications are similar to (even somewhat better than) the LT1014's.

Both the LT1013 and LT1014 can be operated off a single 5V power supply: input common-mode range includes ground; the output can also swing to within a few millivolts of ground. Crossover distortion, so apparent on previous single-supply designs, is eliminated. A full set of specifications is provided with ± 15 V and single 5V supplies.

APPLICATIONS INFORMATION

Single Supply Operation

The LT1013/1014 are fully specified for single supply operation, i.e., when the negative supply is 0V. Input common-mode range includes ground; the output swings within a few millivolts of ground. Single supply operation, however, can create special difficulties, both at the input and at the output. The LT1013/LT1014 have specific circuitry which addresses these problems.

At the input, the driving signal can fall below 0V—inadvertently or on a transient basis. If the input is more than

a few hundred millivolts below ground, two distinct problems can occur on previous single supply designs, such as the LM124, LM158, OP-20, OP-21, OP-220, OP-221, OP-420:

a) When the input is more than a diode drop below ground, unlimited current will flow from the substrate (V^- terminal) to the input. This can destroy the unit. On the LT1013/1014, the 400Ω resistors, in series with the input (see schematic diagram), protect the devices even when the input is 5V below ground.

APPLICATIONS INFORMATION

(b) When the input is more than 400mV below ground (at 25°C), the input stage saturates (transistors Q3 and Q4) and phase reversal occurs at the output. This can cause lock-up in servo systems. Due to a unique phase reversal protection circuitry (Q21, Q22, Q27, Q28), the LT1013/1014's outputs do not reverse, as illustrated below, even when the inputs are at -1.5V.

There is one circumstance, however, under which the phase reversal protection circuitry does not function: when the other op amp on the LT1013, or one specific amplifier of the other three on the LT1014, is driven hard into negative saturation at the output.

Phase reversal protection does not work on amplifier:
 A when D's output is in negative saturation. B's and C's outputs have no effect.
 B when C's output is in negative saturation. A's and D's outputs have no effect.
 C when B's output is in negative saturation. A's and D's outputs have no effect.
 D when A's output is in negative saturation. B's and C's outputs have no effect.

At the output, the aforementioned single supply designs either cannot swing to within 600mV of ground (OP-20) or cannot sink more than a few microamperes while swinging to ground (LM124, LM158). The LT1013/1014's all-NPN output stage maintains its low output resistance and high gain characteristics until the output is saturated.

In dual supply operations, the output stage is crossover distortion-free.

Comparator Applications

The single supply operation of the LT1013/1014 lends itself to its use as a precision comparator with TTL compatible output:

In systems using both op amps and comparators, the LT1013/1014 can perform multiple duties; for example, on the LT1014, two of devices can be used as op amps and the other two as comparators.

Voltage Follower with Input Exceeding the Negative Common-Mode Range

6Vp-p INPUT, -1.5V TO 4.5V

EXHIBIT OUTPUT PHASE
REVERSAL

LT1013/LT1014
NO PHASE REVERSAL

Comparator Rise Response Time 10mV, 5mV, 2mV Overdrives

Comparator Fall Response Time to 10mV, 5mV, 2mV Overdrives

APPLICATIONS INFORMATION

Low Supply Operation

The minimum supply voltage for proper operation of the LT1013/1014 is 3.4V (three Ni-Cad batteries). Typical supply current at this voltage is 290 μ A, therefore power dissipation is only one milliwatt per amplifier.

Noise Testing

For application information on noise testing and calculations, please see the LT1007 or LT1008 data sheet.

Test Circuit for Offset Voltage and Offset Drift with Temperature

*RESISTORS MUST HAVE LOW THERMOELECTRIC POTENTIAL.
 **THIS CIRCUIT IS ALSO USED AS THE BURN-IN CONFIGURATION, WITH SUPPLY VOLTAGES INCREASED TO ± 20 V.
 $V_O = 1000V_{OS}$

TYPICAL APPLICATIONS

50MHz Thermal rms to DC Converter

2% ACCURACY, DC-50MHz.
 100:1 CREST FACTOR CAPABILITY.
 *0.1% RESISTOR.
 T1-T2=YELLOW SPRINGS INST. CO. THERMISTOR COMPOSITE #44018.
 ENCLOSE T1 AND T2 IN STYROFOAM.
 7.5mW DISSIPATION.

5V Single Supply Dual Instrumentation Amplifier

OFFSET = 150 μ V
 GAIN = $\frac{R_2}{R_1} + 1$.
 CMRR = 120 dB.
 COMMON-MODE RANGE IS 0V TO 5V.

TYPICAL APPLICATIONS

Hot Wire Anemometer

Liquid Flowmeter

5V Powered Meter Speed Controller

5V Powered EEPROM Pulse Generator

TYPICAL APPLICATIONS

Methane Concentration Detector with Linearized Output

Low Power 9V to 5V Converter

[illegible]

The circuit diagram shows two LT1013 op-amps, A1 and A2. Op-amp A1 is configured as a voltage follower with its non-inverting input (+) connected to the input signal (0V-4V) through a 2k resistor and a 4mA trimmer. Its inverting input (-) is connected to ground. Op-amp A2 is configured as a voltage follower with its non-inverting input (+) connected to the output of A1 through a 100k resistor and a 68k resistor. Its inverting input (-) is connected to ground. The output of A2 is connected to the primary of a transformer T1 through a 0.1Ω resistor. The secondary of T1 is connected to a bridge rectifier circuit consisting of four 1N4002 diodes and a 10μF capacitor. The output of the rectifier is labeled "4mA-20mA OUT FULLY FLOATING". The circuit is powered by a +5V supply and a -5V supply. A 1.2V diode (LT1004) is connected between the +5V and -5V supplies. A 4.3k resistor is connected between the +5V supply and the input of A1. A 10k* resistor is connected between the input of A1 and ground. A 4k* resistor is connected between the input of A1 and the input of A2. A 301Ω* resistor is connected between the input of A2 and ground. A 1k 20mA trimmer is connected between the input of A2 and ground. A 2k 4mA trimmer is connected between the input of A1 and ground. The text "† 8-BIT ACCURACY." is printed below the transformer.

TYPICAL APPLICATIONS

5V Powered, Linearized Platinum RTD Signal Conditioner

ALL RESISTORS ARE TRW-MAR-6 METAL FILM.

High Speed, Precision JFET Input Operational Amplifier

FEATURES

- **Guaranteed Slew Rate** 23V/μs Min.
- **Guaranteed Offset Voltage** 250μV Max.
–55°C to 125°C 750μV Max.
- **Guaranteed Drift** 5μV/°C Max.
- **Guaranteed Bias Current** 180pA Max.
70°C 4nA Max.
125°C
- **Gain-Bandwidth Product** 8.5MHz Typ.
- **Settling Time to 0.05% (10V Step)** 0.9μs Typ.

APPLICATIONS

- Fast D/A Output Amplifiers (12, 14, 16 Bits)
- High Speed Instrumentation
- Fast, Precision Sample and Hold
- Voltage-to-Frequency Converters
- Logarithmic Amplifiers

DESCRIPTION

The LT1022 JFET input operational amplifier combines high speed and precision performance.

A 26V/μs slew rate and 8.5MHz gain-bandwidth product are simultaneously achieved with offset voltage of typically 80μV, 1.5μV/°C drift, bias currents of 50pA at 70°C, 500pA at 125°C. The output delivers 20mA of load current without gain degradation.

The 250μV maximum offset voltage specification represents less than 1/2 least significant bit error in a 14-bit, 10V system.

The LT1022A meets or exceeds all OP-16A and OP-16E specifications. It is faster and more accurate without stability problems at cold temperatures.

The LT1022 can be used as the output amplifier for 12-bit current output D/A converters, as shown below.

For a more accurate, lower power dissipation, but slower JFET input op amp, please refer to the LT1055 data sheet.

12-Bit Voltage Output D/A Converter

$C_F = 15\text{pF TO } 33\text{pF}$
SETTLING TIME TO 2mV (0.8 LSB) = 1.5μs TO 2μs

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Offset voltage is measured under two different conditions:

- (a) approximately 0.5 seconds after application of power;
- (b) at $T_A = 25^\circ C$, with the chip self-heated to approximately $45^\circ C$ to account for chip temperature rise when the device is fully warmed up.

Note 2: 10Hz noise voltage density is sample tested on every lot of A grades. Devices 100% tested at 10Hz are available on request.

Note 3: This parameter is tested on a sample basis only.

Note 4: Current noise is calculated from the formula: $i_n = (2qI_B)^{1/2}$, where $q = 1.6 \times 10^{-19}$ coulomb. The noise of source resistors up to $1G\Omega$ swamps the contribution of current noise.

Note 5: Offset voltage drift with temperature is practically unchanged when the offset voltage is trimmed to zero with a 100k potentiometer between the balance terminals and the wiper tied to V^+ . Devices tested to tighter drift specifications are available on request.

TYPICAL PERFORMANCE CHARACTERISTICS

Small Signal Response

The typical behavior of many LT1022 parameters is identical to the LT1056. Please refer to the LT1055/1056 data sheet for the following typical performance characteristics:

- Input Bias and Offset Currents vs Temperature
- Input Bias Current Over the Common-Mode Range
- Distribution of Input Offset Voltage (H and N8 Package)
- Distribution of Offset Voltage Drift with Temperature
- Warm-Up Drift
- Long Term Drift of Representative Units
- 0.1Hz to 10Hz Noise
- Voltage Noise vs Frequency
- Noise vs Chip Temperature

- Output Impedance vs Frequency
- Common-Mode Range vs Temperature
- Common-Mode and Power Supply Rejections vs Temperature
- Common-Mode Rejection Ratio vs Frequency
- Power Supply Rejection Ratio vs Frequency
- Voltage Gain vs Temperature
- Supply Current vs Supply Voltage
- Output Swing vs Load Resistance
- Short Circuit Current vs Time

The circuit diagram illustrates a 20Hz to 2MHz TTL output converter. It begins with an LM329 photodiode connected to a light input. The signal is processed by an LT1022 op-amp, which is configured with a 10MΩ feedback resistor and a 100kΩ output resistor. The output of the LT1022 is connected to the input of an LT1011 op-amp. The LT1011 is configured with a 1.8kΩ feedback resistor and a 100kΩ output resistor. The output of the LT1011 is connected to the input of an LT1004 precision centred zero. The LT1004 is configured with a 1.8kΩ feedback resistor and a 100kΩ output resistor. The final output is a TTL signal with a frequency range of 20Hz to 2MHz.

Dual, Matched Picoampere, Microvolt Input, Low Noise Op Amp

FEATURES

- **Guaranteed Offset Voltage** 50 μ V Max.
- **Guaranteed Bias Current** 120pA Max.
25°C 700pA Max.
–55°C to 125°C 1.5 μ V/°C Max.
- **Guaranteed Drift** 0.5 μ Vp-p
- **Low Noise, 0.1Hz to 10Hz** 600 μ A Max.
- **Guaranteed Supply Current** 112dB Min.
- **Guaranteed CMRR** 112dB Min.
- **Guaranteed PSRR** 112dB Min.
- **Guaranteed Voltage Gain with 5mA Load Current**
- **Guaranteed Matching Characteristics**

APPLICATIONS

- Strain Gauge Signal Conditioner
- Dual Limit Precision Threshold Detection
- Charge Integrators
- Wide Dynamic Range Logarithmic Amplifiers
- Light Meters
- Low Frequency Active Filters
- Standard Cell Buffers
- Thermocouple Amplifiers

DESCRIPTION

The LT1024 dual, matched internally compensated universal precision operational amplifier can be used in practically all precision applications requiring multiple op amps. The LT1024 combines picoampere bias currents (which are maintained over the full –55°C to 125°C temperature range), microvolt offset voltage (and low drift with time and temperature), low voltage and current noise, and low power dissipation. Extremely high common-mode and power supply rejection ratios, practically immeasurable warm-up drift, and the ability to deliver 5mA load current with a voltage gain of a million round out the LT1024's superb precision specifications.

Tight matching is guaranteed on offset voltage, non-inverting bias currents and common-mode and power supply rejections.

The all-around excellence of the LT1024 eliminates the necessity of the time-consuming error analysis procedure of precision system design in many dual applications; the LT1024 can be stocked as the universal dual op amp in the 14-pin DIP configuration.

For a single op amp with similar specifications, see the LT1012 data sheet; for a single supply dual precision op amp in the 8-pin configuration, see the LT1013 data sheet.

Two Op Amp Instrumentation Amplifier

$$\text{GAIN} = \frac{R_4}{R_3} \left[1 + \frac{1}{2} \left(\frac{R_2}{R_1} + \frac{R_3}{R_4} \right) + \frac{R_2 + R_3}{R_5} \right] \approx 100$$

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Differential input voltages greater than 1V will cause excessive current to flow through the input protection diodes unless limiting resistance is used.

Note 2: The V^+ supply terminals are completely independent and may be powered by separate supplies if desired (this approach, however, would sacrifice the advantages of the power supply rejection ratio matching). The V^- supply terminals are both connected to the common substrate and must be tied to the same voltage. Both V^- pins should be used.

Note 3: This parameter is tested on a sample basis only.

Optional Offset Nulling Circuit

APPLICATIONS INFORMATION

The LT1024 may be inserted directly into OP-10, OP-207 or OP227 sockets with or without removal of external nulling components.

The LT1024 is specified over a wide range of power supply voltages from $\pm 2\text{V}$ to $\pm 18\text{V}$. Operation with lower supplies is possible down to $\pm 1.2\text{V}$ (two NiCad batteries).

Advantages of Matched Dual Op Amps

In many applications, the performance of a system depends on the matching between two operational amplifiers rather than the individual characteristics of the two op amps. Two or three op amp instrumentation amplifiers, tracking voltage references, and low drift active filters are some of the circuits requiring matching between two op amps.

The well-known triple op amp configuration illustrates these concepts. Output offset is a function of the difference between the offsets of the two halves of the LT1024. This error cancellation principle holds for a considerable number of input-referred parameters in addition to offset voltage and its drift with temperature. Input bias current will be the average of the two non-inverting input currents (I_B^+). The difference between these two cur-

rents (I_{OS}^+) is the offset current of the instrumentation amplifier. Common-mode and power supply rejections will be dependent only on the match between the two amplifiers (assuming perfect resistor matching).

The concepts of common-mode and power supply rejection ratio match (ΔCMRR and ΔPSRR) are best demonstrated with a numerical example:

Assume $\text{CMRR}_A = +1.0\mu\text{V/V}$ or 120dB and $\text{CMRR}_B = +0.5\mu\text{V/V}$ or 126dB, then $\Delta\text{CMRR} = 0.5\mu\text{V/V}$ or 126dB if $\text{CMRR}_B = -0.5\mu\text{V/V}$, which is still 126dB, then $\Delta\text{CMRR} = 1.5\mu\text{V/V}$ or 116.5dB.

Typical performance of the instrumentation amplifier:

Input offset voltage = $25\mu\text{V}$.

Input bias current = 30pA .

Input resistance = $10^{12}\Omega$.

Input offset current = 30pA .

Input noise = $0.7\mu\text{Vp-p}$.

Power bandwidth ($V_O = \pm 10\text{V}$) = 80kHz.

Clearly, the LT1024, by specifying and guaranteeing all of these matching parameters, can significantly improve the performance of matching dependent circuits.

Three Op Amp Instrumentation Amplifier

APPLICATIONS INFORMATION

Achieving Picoampere/Microvolt Performance

In order to realize the picoampere/microvolt level accuracy of the LT1024, proper care must be exercised. For example, leakage currents in circuitry external to the op amp can significantly degrade performance. High quality insulation should be used (e.g., Teflon, Kel-F); cleaning of all insulating surfaces to remove fluxes and other residues will probably be required. Surface coating may be necessary to provide a moisture barrier in high humidity environments.

Board leakage can be minimized by encircling the input circuitry with a guard ring operated at a potential close to that of the inputs: in inverting configurations, the guard ring should be tied to ground, in non-inverting connections, to the inverting input. Guarding both sides of the printed circuit board is required. Bulk leakage reduction depends on the guard ring width. Nanoampere level leakage into the offset trim terminals can affect offset voltage and drift with temperature.

Microvolt level error voltages can also be generated in the external circuitry. Thermocouple effects caused by temperature gradients across dissimilar metals at the contacts to the input terminals can exceed the inherent drift of the amplifier. Air currents over device leads should be minimized, package leads should be short, and the two input leads should be as close together as possible and maintained at the same temperature.

Test Circuit for Offset Voltage and its Drift with Temperature

Direct Pressure Transducer to Digital Output Signal Conditioner

FEATURES

- **Guaranteed** Max. Offset $5\mu\text{V}$
- **Guaranteed** Max. Offset Drift $0.05\mu\text{V}/^\circ\text{C}$
- **Typ.** Offset Drift $0.01\mu\text{V}/^\circ\text{C}$
- **Excellent** Long Term Stability $100\text{nV}/\sqrt{\text{Month}}$
- **Guaranteed** Max. Input Bias Current 30pA
- **Over Operating Temperature Range**
 - Guaranteed** Min. Gain 120dB
 - Guaranteed** Min. CMRR 120dB
 - Guaranteed** Min. PSRR 120dB
- **Single Supply Operation** 4.75V to 16V
(Input Voltage Range Extends to Ground)
- **External Capacitors can be Returned to V^- with No Noise Degradation**

APPLICATIONS

- Thermocouple Amplifiers
- Strain Gauge Amplifiers
- Low Level Signal Processing
- Medical Instrumentation

DESCRIPTION

The LTC1052 and LTC7652 are low noise Chopper-stabilized op amps (CSOA™) manufactured using Linear Technology's enhanced LTCMOS™ silicon gate process. Chopper-stabilization constantly corrects offset voltage errors. Both initial offset and changes in the offset due to time, temperature and common-mode voltage are corrected. This, coupled with picoampere input currents, gives these amplifiers unmatched performance.

Low frequency ($1/f$) noise is also improved by the chopping technique. Instead of increasing continuously at a $3\text{dB}/\text{octave}$ rate, the internal chopping causes noise to decrease at low frequencies.

The chopper circuitry is entirely internal and completely transparent to the user. Only two external capacitors are required to alternately sample and hold the offset correction voltage and the amplified input signal. Control circuitry is brought out on the 14-pin version to allow the sampling of the LTC1052 to be synchronized with an external frequency source.

Ultra Low Noise, Low Drift Amplifier

	Clamp Off Current	$-4V < V_{OUT} < +4V$	●	10	100 2		10	100 1	pA nA

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Absolute Maximum Ratings are those values beyond which the life of the device may be impaired.

Note 2: Connecting any terminal to voltages greater than V^+ or less than V^- may cause destructive latch-up. It is recommended that no sources operating from external supplies be applied prior to power-up of the LTC1052/LTC7652.

Note 3: These parameters are guaranteed by design. Thermocouple effects preclude measurement of these voltage levels in high speed automatic testing. V_{OS} is measured to a limit determined by test equipment capability. Voltages on C_{EXTA} and C_{EXTB} , A_{VOL} , $CMRR$ and $PSRR$ are measured to insure proper operation of the nulling loop to insure meeting the V_{OS} and V_{OS} drift specifications. See Package-Induced V_{OS} in applications section.

Note 4: Output clamp not connected.

Note 5: Current noise is calculated from the formula: $i_n = (2q I_B)^{1/2}$, where $q = 1.6 \times 10^{-19}$ coulomb.

THEORY OF OPERATION

DC OPERATION

The shaded portion of the LTC1052 block diagram (Figure 1) entirely determines the amplifier's DC characteristics. During the auto-zero portion of the cycle, the inputs are shorted together and a feedback path is closed around the input stage to null its offset. Switch S2 and capacitor C_{EXTA} act as a sample and hold to store the nulling voltage during the next step—the sampling cycle.

In the sampling cycle, the zeroed amplifier is used to amplify the differential input voltage. Switch S2 connects the amplified input voltage to C_{EXTB} and the output gain stage. C_{EXTB} and S2 act as a sample and hold to store the amplified input signal during the auto-zero cycle. By switching between these two states at a frequency much higher than the signal frequency, a continuous output results.

Notice that during the auto-zero cycle the inputs are not only shorted together, but are also shorted to the negative input. This forces nulling with the common-mode voltage present and accounts for the extremely high CMRR of the LTC1052. In the same fashion, variations in power supply are also nulled. For nulling to take place, the offset voltage, common-mode voltage and power supply must not change at a frequency which is high compared to the frequency response of the nulling loop.

AC OPERATION AND ALIASING ERRORS

So far, the DC performance of the LTC1052 has been explained. As the input signal frequency increases, the problem of aliasing must be addressed. Aliasing is the spurious formation of low and high frequency signals caused by the mixing of the input signal with the sampling frequency, f_s . The frequency of the error signals, f_E , is:

$$f_E = f_s \pm f_I$$

where f_I = input signal frequency.

Normally it is the difference frequency ($f_s - f_I$) which is of concern because the high frequency ($f_s + f_I$) can be easily filtered. As the input frequency approaches the sampling frequency, the difference frequency approaches zero and will cause DC errors—the exact problem that the chopping amplifier is meant to eliminate.

The solution is simple. Filter the input so the sampling loop never sees any frequency near the sampling frequency.

At a frequency well below the sampling frequency, the LTC1052 forces I_1 to equal I_2 (see Figure 1B). This makes δI zero, thus the gain of the sampling loop zero at this and higher frequencies—i.e., a low pass filter. The corner frequency of this low pass filter is set by the output stage pole ($1/R_{L4} g_{m5} R_{L5} C_2$).

THEORY OF OPERATION

For frequencies above this pole, I_2 is:

$$I_2 = V_{IN} g_{m6} \times \frac{1}{SC2} \times SC1$$

and

$$I_1 - I_2 = V_{IN} g_{m1} - V_{IN} g_{m6} \times \frac{C1}{C2}$$

The LTC1052 is very carefully designed so that $g_{m1} = g_{m6}$ and $C1 = C2$. Substituting these values in the above equation shows $I_1 - I_2 = 0$.

The g_{m6} input stage, with $C1$ and $C2$, not only filters the input to the sampling loop, but also acts as a high frequency path to give the LTC1052 good high frequency response. The unity-gain cross frequencies for both the DC path and high frequency path are identical

$$[f_{3dB} = \frac{1}{2\pi} (g_{m1}/C1) = \frac{1}{2\pi} (g_{m6}/C2)].$$

This makes the frequency response smooth and continuous and eliminates sampling noise in the output as the loop transitions from the high gain DC loop to the high frequency loop.

The typical curves show just how well the amplifier works. The output spectrum shows the difference frequency ($f_1 - f_s = 100\text{Hz}$) is down by 80dB and the frequency response curve shows no abnormalities or perturbations. Also note the well-behaved small and large signal step responses and the absence of the sampling frequency in the output spectrum. If the dynamics of the amplifier, i.e., slew rate and overshoot, depend on the sampling clock, the sampling frequency will appear in the output spectrum.

Figure 1. LTC1052 Block Diagram

APPLICATIONS INFORMATION

EXTERNAL CAPACITORS

CEXTA and CEXTB are the holding elements of a sample and hold circuit. The important capacitor characteristics are leakage current and dielectric absorption. A high quality film-type capacitor such as mylar or polypropylene provides excellent performance. However, low grade capacitors such as ceramic are suitable in many applications.

Capacitors with very high dielectric absorption (ceramic) can take several seconds to settle after power is first turned on. This settling appears as clock ripple on the output and, as the capacitor settles, the ripple gradually disappears. If fast settling after power turn-on is important, mylar or polypropylene is recommended.

Above 85°C, leakage, both from the holding capacitors and the printed circuit board, becomes important. To maintain the capabilities of the LTC1052 it may be necessary to use Teflon™ capacitors and Teflon standoffs when operating at 125°C (see Achieving Picoampere/Microvolt Performance).

CEXTA and CEXTB are normally in the range of 0.1μF to 1.0μF. All specifications are guaranteed with 0.1μF and the broadband noise (see typical photos) is only very slightly degraded with 0.1μF. Output clock ripple is not present for capacitors of 0.1μF or greater at any temperature.

On competitive devices, connecting CEXTA and CEXTB to V⁻ causes an increase in amplifier noise. Design changes have eliminated this problem on the LTC1052. On the 14-pin LTC1052 and 8-pin LTC7652, the capacitors can be returned to V⁻ or CRETURN with no change in noise performance.

ACHIEVING PICOAMPERE/MICROVOLT PERFORMANCE

Picoamperes

In order to realize the picoampere level of accuracy of the LTC1052, proper care must be exercised. Leakage currents in circuitry external to the amplifier can significantly degrade performance. High quality insulation should be used (e.g., Teflon, Kel-F); cleaning of all insulating surfaces to remove fluxes and other residues will probably be

necessary—particularly for high temperature performance. Surface coating may be necessary to provide a moisture barrier in high humidity environments.

Board leakage can be minimized by encircling the input connections with a guard ring operated at a potential close to that of the inputs: in inverting configurations the guard ring should be tied to ground; in non-inverting connections to the inverting input. Guarding both sides of the printed circuit board is required. Bulk leakage reduction depends on the guard ring width.

Microvolts

Thermocouple effects must be considered if the LTC1052's ultra low drift is to be fully utilized. Any connection of dissimilar metals forms a thermoelectric junction producing an electric potential which varies with temperature (Seebeck effect). As temperature sensors, thermocouples exploit this phenomenon to produce useful information. In low drift amplifier circuits the effect is a primary source of error.

Connectors, switches, relay contacts, sockets, resistors, solder, and even copper wire are all candidates for thermal EMF generation. Junctions of copper wire from different manufacturers can generate thermal EMFs of 200nV/°C—4 times the maximum drift specification of

APPLICATIONS INFORMATION

the LTC1052. The copper/kovar junction, formed when wire or printed circuit traces contact a package lead, has a thermal EMF of approximately $35\mu\text{V}/^\circ\text{C}$ —700 times the maximum drift specification of the LTC1052.

Minimizing thermal EMF-induced errors is possible if judicious attention is given to circuit board layout and component selection. It is good practice to minimize the number of junctions in the amplifier's input signal path. Avoid connectors, sockets, switches and relays where possible. In instances where this is not possible, attempt to balance the number and type of junctions so that differential cancellation occurs. Doing this may involve deliberately introducing junctions to offset unavoidable junctions.

Figure 2 is an example of the introduction of an unnecessary resistor to promote differential thermal balance. Maintaining compensating junctions in close physical proximity will keep them at the same temperature and reduce thermal EMF errors.

When connectors, switches, relays and/or sockets are necessary they should be selected for low thermal EMF activity. The same techniques of thermally balancing and coupling the matching junctions are effective in reducing the thermal EMF errors of these components.

Resistors are another source of thermal EMF errors. Table I shows the thermal EMF generated for different resistors. The temperature gradient across the resistor is important,

not the ambient temperature. There are two junctions formed at each end of the resistor and if these junctions are at the same temperature, their thermal EMFs will cancel each other. The thermal EMF numbers are approximate and vary with resistor value. High values give higher thermal EMF.

When all of these errors are considered, it may seem impossible to take advantage of the extremely low drift specifications of the LTC1052. To show that this is not the case, examine the temperature test circuit of Figure 3. The lead lengths of the resistors connected to the amplifier's inputs are identical. The thermal capacity and thermal resistance each input sees is balanced because of the symmetrical connection of resistors and their identical size. Thermal EMF-induced shifts are equal in phase and amplitude, thus cancellation occurs.

Figure 4 shows the response of this circuit under temperature transient conditions. Metal film resistors and an 8-pin DIP socket were used. Care was taken in the construction to thermally balance the inputs to the amplifier. The units were placed in an oven and allowed to stabilize at 25°C . The recording was started, and after 100 seconds the oven, pre-set to 125°C , was switched on. The test was first performed on an 8-pin plastic package and then was repeated for a TO-5 package plugged into the same test board. It is significant that the change in V_{OS} , even under these severe thermal transient conditions, is quite good. As temperature stabilizes, note that the steady-state change of V_{OS} is well within the maximum $\pm 0.05\mu\text{V}/^\circ\text{C}$ drift specification.

Table I. Resistor Thermal EMF

Resistor Type	Thermal EMF/ $^\circ\text{C}$ Gradient
Tin Oxide	$\sim \text{mV}/^\circ\text{C}$
Carbon Composition	$\sim 450\mu\text{V}/^\circ\text{C}$
Metal Film	$\sim 20\mu\text{V}/^\circ\text{C}$
Wire Wound	
Evenohm	$\sim 2\mu\text{V}/^\circ\text{C}$
Manganin	$\sim 2\mu\text{V}/^\circ\text{C}$

Figure 2

APPLICATIONS INFORMATION

Very slight air currents can still affect even this arrangement. Figure 5 shows strip charts of output noise with the circuit covered and with no cover in "still" air. This data illustrates why it is often prudent to enclose the LTC1052 and its attendant components inside some form of thermal baffle.

Figure 3. Offset Drift Test Circuit

PACKAGE-INDUCED OFFSET VOLTAGE

Since the LTC1052 is constantly fixing its own offset, it may be asked why there is any error at all, even under transient temperature conditions. The answer is simple. The LTC1052 can only fix offsets inside its own nulling loop. There are many thermal junctions outside this loop that cannot be distinguished from legitimate signals.

Figure 4. Transient Response of Offset Drift Test Circuit with 100°C Temperature Step

Figure 5. DC to 1Hz (Test Circuit TC3)

APPLICATIONS INFORMATION

Some have been discussed previously, but the package thermal EMF effects are an important source of errors.

Notice the difference in the thermal response curves of Figure 4. This can only be attributed to the package since everything else is identical. In fact, the V_{OS} specification is set by the package-induced warm-up drift, not by the LTC1052. TO-99 metal cans exhibit the worst warm-up drift and Linear Technology sample tests TO-99 lots to minimize this problem.

Two things make 100% screening costly: (1) the extreme precision required on the LTC1052 and (2) the thermal time constant of the package is 0.5 to 3 minutes, depending on package type. The first precludes the use of automatic handling equipment and the second takes a long time. Bench test equipment is available to 100% test for warmed-up drift if offsets of less than $\pm 5\mu V$ are required.

CLOCK

The LTC1052 has an internal clock, setting the nominal sampling frequency at 330Hz. On 8-pin devices there is no way to control the clock externally. In some applications it may be desirable to control the sampling clock and this is the function of the 14-pin device.

CLK IN, CLK OUT and INT/ $\overline{\text{EXT}}$ are provided to accomplish this. With no external connection, an internal pull-up holds INT/ $\overline{\text{EXT}}$ at the V^+ supply and the 14-pin device self-oscillates at 330Hz. In this mode there is a signal on the CLK IN pin of 660Hz (2 times sampling frequency) with a 30% duty cycle. A divide-by-two drives the CLK OUT pin and sets the sampling frequency.

To use an external clock, connect INT/ $\overline{\text{EXT}}$ to V^- and the external clock to CLK IN. The logic threshold of CLK IN is 2.5V below the positive supply. This allows CMOS logic to drive it directly with logic supplies of V^+ and ground. CLK IN can be driven from V^+ to V^- if desired. The duty cycle of the external clock is not particularly critical but should be kept between 30% and 60%.

Capacitance between CLK IN and CLK OUT (pins 13 and 12) can cause the divide-by-two circuit to malfunction. To avoid this, keep this capacitance below 5pF.

OUTPUT CLAMP

If the LTC1052 is driven into saturation, the nulling loop, attempting to force the differential input voltage to zero, will drive CEXTA and CEXTB to a supply rail. After the saturating drive is removed, the capacitors take a finite time to recover—this is the overload recovery time. The overload recovery is longest when the capacitors are driven to the negative rail (see Overload Recovery in typical performance section). The overload recovery time in this case is typically 225ms. In the opposite direction, i.e., CEXTA and CEXTB at positive rail, it is about ten times faster (25ms). The overload recovery time for the LTC1052 is much faster than competitive devices, but if a faster overload recovery time is necessary, the output clamp function can be used.

When the output clamp is connected to the negative input it prevents the amplifier from saturating and thus keeps CEXTA and CEXTB at their nominal voltages. The output clamp is a switch that turns on when the output gets to within approximately 1V of either supply rail. This switch is in parallel with the amplifier's feedback resistor and as the output moves closer to the rail, the switch on resistance decreases, reducing the closed loop gain. The output swing is reduced when the clamp function is used.

How much current the output clamp leaks when off is important because, when used, it is connected to the amplifier's negative input. Any current acts like input bias current and will degrade accuracy. At the other extreme, the maximum current the clamp conducts when on determines how much overdrive the clamp will take and still keep the amplifier from saturating. Both of these numbers are guaranteed in the table of electrical characteristics.

LOW SUPPLY OPERATION

The minimum supply voltage for proper operation of the LTC1052 is typically 4.0V ($\pm 2.0V$). In single supply applications, PSRR is guaranteed down to 4.7V ($\pm 2.35V$). This assures proper operation down to the minimum TTL specified voltage of 4.75V.

- Photodiode Amplifiers
- Voltage to Frequency Converters
- Frequency to Voltage Converters
- Fast, Precision Sample and Hold

DESCRIPTION

The LT1055/1056 JFET input operational amplifiers combine precision specifications with high speed performance.

For the first time, $16\text{V}/\mu\text{s}$ slew rate and 6.5MHz gain-bandwidth product are simultaneously achieved with offset voltage of typically $50\mu\text{V}$, $1.2\mu\text{V}/^\circ\text{C}$ drift, bias currents of 40pA at 70°C and 500pA at 125°C .

The 150 μ V maximum offset voltage specification is the best available on any JFET input operational amplifier.

The LT1055 and LT1056 are differentiated by their operating currents. The lower power dissipation LT1055 achieves lower bias and offset currents and offset voltage. The additional power dissipation of the LT1056 permits higher slew rate, bandwidth and faster settling time with a slight sacrifice in DC performance.

The voltage to frequency converter shown below is one of the many applications which utilize both the precision and high speed of the LT1055/1056.

For a JFET input op amp with $23\text{V}/\mu\text{s}$ guaranteed slew rate, refer to the LT1022 data sheet.

The ● denotes the specifications which apply over the full operating temperature range.

For MIL-STD components, please refer to LTC883 data sheet for test listing and parameters.

Note 1: Offset voltage is measured under two different conditions:

(a) approximately 0.5 seconds after application of power; (b) at $T_A = 25^\circ C$ only, with the chip heated to approximately $38^\circ C$ for the LT1055 and to $45^\circ C$ for the LT1056, to account for chip temperature rise when the device is fully warmed up.

Note 2: 10Hz noise voltage density is sample tested on every lot of A grades. Devices 100% tested at 10Hz are available on request.

Note 3: This parameter is tested on a sample basis only.

Note 4: Current noise is calculated from the formula: $i_n = (2qI_B)^{1/2}$, where $q = 1.6 \times 10^{-19}$ coulomb. The noise of source resistors up to 16 Ω swamps the contribution of current noise.

Note 5: Offset voltage drift with temperature is practically unchanged when the offset voltage is trimmed to zero with a 100k potentiometer between the balance terminals and the wiper tied to V^+ . Devices tested to tighter drift specifications are available on request.

APPLICATIONS INFORMATION

The LT1055/1056 may be inserted directly into LF155A/355A, LF156A/356A, OP-15 and OP-16 sockets. Offset nulling will be compatible with these devices with the wiper of the potentiometer tied to the positive supply.

Offset Nulling

No appreciable change in offset voltage drift with temperature will occur when the device is nulled with a potentiometer, R_p , ranging from 10k to 200k.

The LT1055/1056 can also be used in LF351, LF411, AD547, AD611, OPA-111, and TL081 sockets, provided that the nulling circuitry is removed. Because of the LT1055/1056's low offset voltage, nulling will not be necessary in most applications.

Achieving Picoampere/Microvolt Performance

In order to realize the picoampere-microvolt level accuracy of the LT1055/1056 proper care must be exercised. For example, leakage currents in circuitry external to the op amp can significantly degrade performance. High quality insulation should be used (e.g. Teflon™, Kel-F); cleaning of all insulating surfaces to remove fluxes and other residues will probably be required. Surface coating may be necessary to provide a moisture barrier in high humidity environments.

Board leakage can be minimized by encircling the input circuitry with a guard ring operated at a potential close to that of the inputs: in inverting configurations the guard ring should be tied to ground, in non-inverting connections to the inverting input at pin 2. Guarding both sides of the printed circuit board is required. Bulk leakage reduction depends on the guard ring width.

Teflon™ is a trademark of DuPont.

The LT1055/1056 has the lowest offset voltage of any JFET input op amp available today. However, the offset voltage and its drift with time and temperature are still not as good as on the best bipolar amplifiers because the transconductance of FETs is considerably lower than that of bipolar transistors. Conversely, this lower transconductance is the main cause of the significantly faster speed performance of FET input op amps.

Offset voltage also changes somewhat with temperature cycling. The AM grades show a typical $20\mu\text{V}$ hysteresis ($30\mu\text{V}$ on the M grades) when cycled over the -55°C to 125°C temperature range. Temperature cycling from 0°C to 70°C has a negligible (less than $10\mu\text{V}$) hysteresis effect.

The offset voltage and drift performance are also affected by packaging. In the plastic N8 package the molding compound is in direct contact with the chip, exerting pressure on the surface. While NPN input transistors are largely unaffected by this pressure, JFET device matching and drift are degraded. Consequently, for best DC performance, as shown in the typical performance distribution plots, the TO-5 H package is recommended.

Noise Performance

The current noise of the LT1055/1056 is practically immeasurable at $1.8\text{fA}/\sqrt{\text{Hz}}$. At 25°C it is negligible up to $1\text{G}\Omega$ of source resistance, R_s (compared to the noise of R_s). Even at 125°C it is negligible to $100\text{M}\Omega$ of R_s .

APPLICATIONS INFORMATION

The voltage noise spectrum is characterized by a low $1/f$ corner in the 20Hz to 30Hz range, significantly lower than on other competitive JFET input op amps. Of particular interest is the fact that, with any JFET IC amplifier, the frequency location of the $1/f$ corner is proportional to the square root of internal gate leakage currents and, therefore, noise doubles every 20°C . Furthermore, as illustrated in the noise versus chip temperature curves, the 0.1Hz to 10Hz peak-to-peak noise is a strong function of temperature, while wideband noise ($f_0 = 1\text{kHz}$) is practically unaffected by temperature.

Consequently, for optimum low frequency noise, chip temperature should be minimized. For example, operating an LT1056 at $\pm 5V$ supplies or with a $20^{\circ}C/W$ case-to-ambient heat sink reduces 0.1Hz to 10Hz noise from typically $2.5\mu V_{p-p}$ ($\pm 15V$, free-air) to $1.5\mu V_{p-p}$. Similarly, the noise of an LT1055 will be $1.8\mu V_{p-p}$ typically because of its lower power dissipation and chip temperature.

High Speed Operation

Settling time is measured in the test circuit shown. This test configuration has two features which eliminate problems common to settling time measurements: (1) probe capacitance is isolated from the "false summing" node, and (2) it does not require a "flat top" input pulse since

the input pulse is merely used to steer current through the diode bridges. For more details, please see Application Note 10.

As with most high speed amplifiers, care should be taken with supply decoupling, lead dress and component placement.

When the feedback around the op amp is resistive (R_F), a pole will be created with R_F , the source resistance and capacitance (R_S , C_S), and the amplifier input capacitance ($C_{IN} \approx 4\text{pF}$). In low closed loop gain configurations and with R_S and R_F in the kilohm range, this pole can create excess phase shift and even oscillation. A small capacitor (C_F) in parallel with R_F eliminates this problem. With $R_S(C_S + C_{IN}) = R_F C_F$, the effect of the feedback pole is completely removed.

JFET-Input Operational Amplifiers Low Supply Current (LF155) High Speed (LF156)

FEATURES

- *Guaranteed* Offset Voltage Drift on All Grades
- *Guaranteed* Slew Rate on All Grades
- *Guaranteed* Low Input Offset Current 10pA Max.
- *Guaranteed* Low Input Bias Current 50pA Max.
- *Guaranteed* High Slew Rate (156A/356A) 10V/ μ s Min.
- Fast Settling to 0.01% 1.5 μ s

APPLICATIONS

- Output Amplifiers for D/A Converters
- Fast Sample and Hold Circuits
- High Speed Integrators
- Photocell Amplifiers
- High Input Impedance Buffers

DESCRIPTION

Linear Technology's LF155/156 series features several improvements compared to similar types from other manufacturers: offset voltage drift with temperature and slew rate are guaranteed on all grades, not just on the more expensive "A" grades. Other specifications such as voltage gain and high temperature bias and offset currents are also improved.

The industry standard LF155/156 devices exhibit phase reversal at the output when the negative common-mode limit at the input is exceeded (i.e., from -12 V to -15 V with ± 15 V supplies). This can cause lock-up in servo systems. As shown below, Linear Technology's LF155/156 does not have this problem due to unique phase reversal protection circuitry. For applications requiring higher performance, see the LT1055 and LT1056 data sheets.

The ● denotes the specifications which apply over the full operating temperature range. The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Unless otherwise specified, the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Unless otherwise stated, these test conditions apply:

	LF155A/156A LF155/156	LF355A/356A	LF355/356
Supply Voltage, V_S	$\pm 15V \leq V_S \leq \pm 20V$	$\pm 15V \leq V_S \leq \pm 18V$	$V_S = \pm 15V$
T_A	$-55^\circ C \leq T_A \leq +125^\circ C$	$0^\circ C \leq T_A \leq +70^\circ C$	$0^\circ C \leq T_A \leq +70^\circ C$

and V_{OS} , I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 3: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_J = T_A + \Theta_{JA} P_D$ where Θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 4: The temperature coefficient of the adjusted input offset voltage changes only a small amount ($0.5\mu V/^\circ C$ typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.

Note 5: Settling time is defined here for a unity gain inverter connection using $2k\Omega$ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter.

Low Power Op Amp and Reference

FEATURES

- *Guaranteed* Operation at +1.2V Op Amp and Reference on Single Chip
- Low Supply Current 400 μ A
- Capable of Floating Mode Operation
- Low Reference Drift 20ppm/ $^{\circ}$ C
- Low Offset Voltage
- Output Swings to Within 15mV of Rails

APPLICATIONS

- Remote Signal Conditioner / Transmitter
- Battery Operated Instruments
- Precision Current Regulators
- Precision Voltage Regulators
- Thermocouple Transmitter

DESCRIPTION

The LM10 combines a precision reference, a reference buffer amplifier and an independent, high quality op amp on a single chip. The device is capable of operation from a single supply as low as 1.1V, from dual supplies up to ± 20 V and typically draws 270 μ A supply current. Input voltage range for the op amp includes ground, while the unloaded output can swing to within 15mV of each rail. Further, the LM10 will deliver 20mA output current and still swing within ± 400 mV of the supply rails.

With its low operating current and floating operation capability, the LM10 is ideal for two wire analog transmitter circuits where the processed signal is carried on the same line used for power. The LM10 is suggested for portable battery powered equipment and is fully specified for operation from a single 1.2V battery. Other applications include precision current and voltage regulators, operating from very low voltages to several hundred volts.

The ● denotes the specifications which apply over full operating temperature range.

Note 1: The input voltage can exceed the supply voltages as long as the voltage from the input to any other terminal does not exceed the maximum differential voltage, and the maximum junction temperature is not exceeded due to the excess power dissipation that occurs when the input voltage is less than the negative supply voltage.

Note 2: The maximum operating junction temperatures are: 150°C for the LM10; 100°C for the LM10B and LM10BL; and 85°C for the LM10C and LM10CL. Package derating factors will be found on the back page of this data sheet.

Note 3: These specifications apply for the following conditions unless otherwise noted:

at 25°C

(a) $V^- \leq V_{CM} \leq V^+ - 0.85V$

(b) $1.2V \leq V_S \leq V_{MAX}$

over temperature

$V^- \leq V_{CM} \leq V^+ - 1.0V$

$1.3V \leq V_S \leq V_{MAX}$

$V_{REF} = 0.2V$ and $0 \leq I_{REF} \leq 1.0mA$ where $V_{MAX} = 40V$ for the LM10, LM10B and LM10C and $V_{MAX} = 6.5V$ for the LM10BL and LM10CL. The specifications do not include errors due to thermal gradients ($\tau_1 \approx 20ms$), die heating ($\tau_2 \approx 0.2$ sec) or package heating.

Note 4: For $T_J > 90^\circ C$, I_{OS} may exceed 1.5nA when $V_{CM} = V^-$. When the common-mode input voltage is within 100mV of the negative supply and $T_J = 125^\circ C$, the offset current will be less than 5nA.

Note 5: Shunt gain defines the operation in floating applications when the output is connected to the V^+ terminal and input common-mode is referred to V^- (see typical applications). The effects of larger output voltage swing with higher load resistance can be accounted for by adding the positive supply rejection error.

Note 6: Guaranteed by design.

- *Guaranteed* 2nA Max. Input Bias Current
- *Guaranteed* 600 μ A Max. Supply Current
- *Guaranteed* 0.5mV Max. Offset Voltage
- *Guaranteed* 5 μ V/ $^{\circ}$ C Max. Drift
- Wide Supply Voltage Range: $\pm$ 2V to $\pm$ 20V
- Interchangeable with Other Manufacturers' LH2108

APPLICATIONS

- Integrators
- Transducer Amplifiers
- Analog Memories
- Light Meters

DESCRIPTION

The LH2108A series of precision operational amplifiers is particularly well suited for high source impedance applications requiring low offset and bias currents, as well as low power dissipation. Unlike FET input amplifiers, the offset and bias currents of the LH2108A do not change significantly with temperature variations. Advanced design, processing and testing techniques make Linear's LH2108A a superior choice over previous devices.

For higher performance dual amplifiers, see the LT1024, LT1002, and LT1013 data sheets.

FEATURES

- 30 Volt Differential Input Range
- 75 nA Input Bias Current
- Wide Common Mode Voltage Range

APPLICATIONS

- Signal Conditioning Amplifiers
- Voltage Followers
- Comparators

DESCRIPTION

The LM101A and LM107 are general purpose operational amplifiers, featuring low bias current and the ability to operate with high input differential voltages up to 30 Volts. Unlike many FET input amplifiers, the output of the LM101A/107 does not reverse if the common mode range is exceeded, making them particularly useful in comparator and oscillator circuits.

The LM101A uses external compensation, allowing the frequency response and slew rate to be optimized for the application. The LM107 is identical to the LM101A with the exception that the compensation capacitor is internal. Linear's LM101A and LM107 include improved design and processing techniques resulting in superior long term stability and reliability over previous devices. The curve of bias current versus differential input voltage indicates that a minimal change in input current occurs over a wide range of input signal, which is important in many applications.

The ● denotes the specifications which apply over the full operating temperature range.

For MIL-STD components, please refer to LTC 883 data sheet for test listing and parameters.

Note 1: Differential input voltages greater than 1V will cause excessive current to flow through the input protection diodes unless current limiting resistance is used.

Note 2: For supply voltages less than $\pm 15V$, the maximum input voltage is equal to the supply voltage.

Note 3: Guaranteed by design.

TYPICAL APPLICATIONS

COMPENSATION CIRCUITS

Standard Compensation Circuit

** BANDWIDTH AND SLEW RATE ARE PROPORTIONAL TO $1/C_f$

Alternate* Frequency Compensation

* IMPROVES REJECTION OF POWER SUPPLY NOISE BY A FACTOR OF TEN.

** BANDWIDTH AND SLEW RATE ARE PROPORTIONAL TO $1/C_s$

Feedforward Compensation

TYPICAL PERFORMANCE CHARACTERISTICS

Guaranteed Offset Error

Guaranteed Drift Error

Input Noise Voltage

Open Loop Frequency Response

Large Signal Frequency Response

Voltage Follower Pulse Response

Voltage Gain

Output Swing

Supply Current

TYPICAL PERFORMANCE CHARACTERISTICS

TYPICAL APPLICATIONS

Low Drift Integrator With Reset

* Q1 AND Q3 SHOULD NOT HAVE INTERNAL GATE-PROTECTION DIODES.

Inverting Amplifier With High Input Resistance

TYPICAL APPLICATIONS

Amplifier For Piezoelectric Transducers

Amplifier For Bridge Transducers

Fast* Summing Amplifier

† In addition to increasing speed, the LM101A raises high and low frequency gain, increases output drive capability and eliminates thermal feedback.

* Power Bandwidth: 250 KHz
Small Signal Bandwidth: 3.5 MHz
Slew Rate: 10V/µs

$$\dagger C5 = \frac{6 \times 10^{-8}}{R_f}$$

Bilateral Current Source

Sample and Hold

* Teflon, polyethylene or polycarbonate dielectric capacitor.

Worst case drift
less than 2.5 mV/sec.

Differential Input Instrumentation Amplifier

APPLICATIONS INFORMATION

Input guarding

Input guarding is used to reduce surface leakage. Guarding both sides of the board is required. Bulk leakage reduction is less and depends on the guard ring width.

The guard ring is connected to a low impedance point at same potential as the sensitive input leads. Connections for various op amp configurations are shown below.

INVERTING

FOLLOWER

NON-INVERTING

Input protection

Current is limited by R2 even when input is connected to a voltage source outside the common mode range. If one supply reverses, current is controlled by R1. These resistors do not affect normal operation.

The input resistor controls the current when the input exceeds the supply voltages, when the power for the op amp is turned off, or when the output is shorted.

Offset Voltage Test Circuit†

 $A_v = 1000$

† THIS CIRCUIT IS ALSO USED AS THE BURN-IN CONFIGURATION WITH SUPPLY VOLTAGES EQUAL TO $\pm 20V$, $R_1 = R_3 = 10k$, $R_2 = 200k$, $A_v = 100$.

High Speed Operational Amplifier

FEATURES

- *Guaranteed* 1.0mV Max. Input Offset Voltage
- *Guaranteed* 100,000 Min. Gain
- *Guaranteed* 50V/ μ s Slew Rate
- *Guaranteed* 20nA Max. Input Offset Current
- 15MHz Bandwidth
- Unity Gain Stable

APPLICATIONS

- Wideband Amplifiers
- High Frequency Absolute Value Circuits
- D/A Converter Amplifiers
- Fast Integrators

DESCRIPTION

The LT118A is an improved version of the industry standard LM118. The LT118A features lower input offset voltage, lower input offset currents, higher gain and higher common mode and power supply rejection. Because of these enhancements, the LT118A will improve the accuracy of most applications. Unlike many wideband amplifiers, the LT118A is unity gain stable and has a slew rate of 50V/ μ s. When used in inverting amplifier applications, feedforward compensation can be used to achieve slew rates in excess of 150V/ μ s. Linear Technology Corporation's advanced processing techniques make the LT118A an ideal choice for high speed applications.

The • denotes those specifications which apply over the full operating temperature range.

The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

Note 1: The inputs are shunted with back-to-back zeners for overvoltage protection. Excessive current will flow if a differential voltage greater than 5V is applied to the inputs.

Note 2: For supply voltages less than $\pm 15V$, the maximum input voltage is equal to the supply voltage.

Note 3: These specifications apply for $\pm 5V \leq V_S \leq \pm 20V$. The power supplies must be bypassed with a 0.1 μF or greater disc capacitor within 4 inches of the device.

Settling Time

APPLICATIONS INFORMATION

Because of their wider bandwidth, the LT118A and LM118 operational amplifiers require more application care than most general purpose low frequency amplifiers. One of the most critical requirements is that power supplies should be bypassed with a 0.1 μ F (or larger) disc ceramic capacitor within an inch of the device. Also, stray capacitance at either the input or output can cause oscillation. While input capacitance can be compensated by placing a capacitor across the feedback resistor, load capacitance must be minimized or isolated as shown. Even the 50pF input capacitance of a 1X scope probe can alter the response of the device.

Settling time, an important parameter in many high speed amplifier applications, is difficult to measure and optimize. Settling time is very "application dependent" and is influenced by external components, layout and the amplifier. In general, the settling time to 0.01% can be minimized by using a circuit similar to that shown. In addition to the compensation network shown, a capacitor is needed across the feedback resistor to minimize ringing.

Power supply bypassing can also affect settling time. The amplifier has low power supply rejection ratio at high frequencies, so transients and ringing on the supply leads can appear at the output. Large (22 μ F) solid tantalum capacitors are preferred to minimize supply aberrations.

- Instrumentation Amplifiers
- Medical Instruments

DESCRIPTION

The OP-05 is an internally compensated op-amp which provides excellent input offset voltage, low bias current, very high common mode rejection, and low offset voltage drift with temperature when the input offset voltage is externally trimmed to zero. Direct replacement of similar devices in existing systems can result in significant system performance improvement without redesign. The OP-05 is particularly well suited for instrumentation and low signal level applications where precision and stability over time and temperature are important. Internal frequency compensation enhances the OP-05's versatility for a wide variety of precision op-amp uses. Linear's advanced design, process and test techniques ensure device performance as well as reliability. An instrumentation amplifier application is shown below. For higher performance requirements see the LT1001 single precision op amp and the LT1002 dual matched precision op amp series.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Long term offset voltage stability is the average value of offset voltage vs. time plotted over extended periods following 30 days of operation. Values for time under 30 days of operation are typically 2.5 μV following the first hour of operation.

Note 2: This parameter is sample tested.

Note 3: This parameter is guaranteed by design.

 - 2) OBSERVE OUTPUT FOR 10 SECONDS
- $A_v = 25000$

Application Tip

When the OP-05 is used as a replacement in 725, 108/108A, 308/308A applications, removal of external compensation is optional. For conventionally nulled 741 type applications, external trimming should be removed. Care should be taken to avoid thermocouple voltages caused by temperature variations between the input terminals or dissimilar metals.

TYPICAL APPLICATIONS

Precision Absolute Value Circuit

ALL RESISTORS MATCHED WITHIN 0.1%

Two Op-Amp Instrumentation Amplifier

* ADJUST R1 FOR CMRR, THEN
ADJUST R5 FOR GAIN ACCURACY.
R5 DOES NOT AFFECT CMRR.

FOR MAXIMUM CMRR, $\frac{R_2}{R_1} = \frac{R_3}{R_4}$

FOR THIS CONDITION,

$$V_o = V_{in} \left[\frac{R_4}{R_3} \right] \left[1 + \frac{R_2}{R_1} + \frac{R_2 + R_3}{R_5} \right]$$

$$\frac{V_o}{V_{in}} = 210 \text{ FOR VALUES SHOWN}$$

FEATURES

- *Guaranteed 25 μ V max. Offset Voltage*
- *Guaranteed 0.6 μ V/ $^{\circ}$ C max. Offset Voltage Drift with Temperature*
- *Excellent 1.0 μ V/Month max. Long Term Stability*
- *Guaranteed 0.6 μ V_{p-p} max. Noise*
- *Guaranteed 2.0nA max. Input Bias Current*

APPLICATIONS

- Thermocouple Amplifiers
- Strain Gauge Amplifiers
- Low Level Signal Processing
- Medical Instrumentation

DESCRIPTION

The OP-07 offers excellent performance in applications requiring low offset voltage, low drift with time and temperature and very low noise. Linear's OP-07 is interchangeable with many of the precision op-amp device types. The OP-07 also offers a wide input voltage range, high common mode rejection and low input bias current. These features result in optimum performance for small signal level and low frequency applications. Use of advanced design, processing and testing techniques make Linear's OP-07 a superior choice over similar products. A buffered reference application is shown below. For single op amp applications requiring higher performance, see the LT1001 and for matched dual precision applications see the LT1002.

Precision Buffered Single Supply Reference

The OP-07 contributes less than 5% of the total drift with temperature, noise and long term drift of the reference application.

The ● denotes the specifications which apply over full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Offset voltage for the OP-07A is measured 60 seconds after power is applied. All other grades are measured with high speed test equipment, approximately 1 second after power is applied.

Note 2: This parameter is tested on a sample basis only.

Note 3: Long term Input Offset Voltage Stability refers to the averaged trend line of V_{OS} versus Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 operating days are typically $2.5\mu V$.

Note 4: This parameter is guaranteed by design.

Note 5: The OP-07D is available by special request.

FEATURES

- Improved Specifications Compared to LF155/156 Devices
- *Guaranteed* Low Offset Voltage $500\mu\text{V}$ Max.
- *Guaranteed* Low Offset Drift $5\mu\text{V}/^\circ\text{C}$ Max.
- *Guaranteed* Bias Current Fully Warmed-Up over Temperature
- OP-15: LF156 Speed with LF155 Power Dissipation
 - Guaranteed* Supply Current 4mA Max.
 - Guaranteed* Slew Rate $10\text{V}/\mu\text{s}$ Min.
- OP-16:
 - Guaranteed* Faster Slew Rate $18\text{V}/\mu\text{s}$ Min.
 - No High Frequency Oscillation at Cold Temperatures
- No Phase Reversal when Negative Common-Mode Limit is Exceeded

APPLICATIONS

Long Term Precision Integration
Current to Voltage Conversion
Medical Instrumentation—CAT Scanner
High Speed, Precision Sample and Hold

DESCRIPTION

The OP-15/16 series devices feature distinct advantages over other JFET-input operational amplifiers, in particular compared to LF155/156 types.

The OP-15 has the speed of the LF156 design with the low power dissipation of the slower LF155. The OP-16 is considerably faster. Both devices offer offset voltages as low as 0.5mV , with guaranteed drift of $5\mu\text{V}/^\circ\text{C}$. Input bias current at 125°C is just a few nanoamperes.

Other manufacturers' OP-15/16 (and LF155/156) exhibit phase reversal at the output when the negative common-mode limit at the input is exceeded; i.e., driving from -12V to -15V with $\pm 15\text{V}$ supplies. This can cause lock-up in servo systems. As shown in the application section, Linear Technology's OP-15/16 does not have this problem due to unique phase reversal protection circuitry.

In addition, Linear's OP-16 is free from high frequency oscillation problems at cold temperatures, as is illustrated in the "Voltage Follower Small Signal Pulse Response" photo. For applications requiring higher performance, see the LT1022, LT1055 and LT1056 data sheets.

The ● denotes the specifications which apply over full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Input bias current is specified for two different conditions. The T_J specification is with the junction at ambient temperature; the warmed-up specification is with the device operating in a warmed-up condition at the ambient temperature specified. I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 2: Settling time is defined here for a unity gain inverter connection using $2k\Omega$ resistors. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within a specified percentage of its final value from the time a $10V$ step input is applied to the inverter.

Note 3: Sample tested.

Note 4: Unless otherwise specified, the absolute maximum negative input voltage is equal to the negative power supply voltage.

Low Noise, High Speed Precision Operational Amplifiers

FEATURES

- *Guaranteed* $3.8\text{nV}/\sqrt{\text{Hz}}$ max 1kHz Noise
- *Guaranteed* $5.5\text{nV}/\sqrt{\text{Hz}}$ max 10Hz Noise
- Very Low Peak-to-Peak Noise, 80nV Typical
- *Guaranteed* $25\mu\text{V}$ max Offset Voltage
- *Guaranteed* $0.6\mu\text{V}/^\circ\text{C}$ max Drift with Temperature
- *Guaranteed* $11\text{V}/\mu\text{sec}$ min Slew Rate (OP-37)
- *Guaranteed* 1 Million min Voltage Gain

APPLICATIONS

- Low Level Transducer Amplifiers
- Precision Threshold Detectors
- Tape Head Preamplifiers
- Microphone Preamplifiers
- Direct Coupled Audio Gain Stages

DESCRIPTION

The OP-27/OP-37 series of operational amplifiers combine outstanding noise performance with excellent precision and high speed specifications. The wideband noise is only $3\text{nV}/\sqrt{\text{Hz}}$, and with the $1/f$ noise corner at 2.7Hz, low noise is maintained for all low frequency instrumentation applications. Precision DC specifications match or exceed the best available op amps: offset voltage is $10\mu\text{V}$, drift with temperature and time are $0.2\mu\text{V}/^\circ\text{C}$ and $0.2\mu\text{V}/\text{month}$, respectively; common mode rejection is 126dB, voltage gain is two million. The unity gain compensated OP-27 is an order of magnitude faster than other precision op amps. The decoupled OP-37 is even faster at a gain-bandwidth product of 63MHz and $17\text{V}/\mu\text{sec}$ slew rate. These characteristics plus Linear Technology's advanced process and test techniques make the OP-27/37 an excellent choice for performance and reliability in all low noise, precision amplifier applications. In addition, Linear's OP-37 is completely latch-up free in high gain, large capacitive feedback configurations. The accurate, microvolt, low noise signal handling capabilities of the OP-27/37 are taken advantage of in the multiplexed thermocouple application shown.

For applications requiring higher performance, see the LT1007 and LT1037 data sheets.

Low Noise, Multiplexed Thermocouple Amplifier

If 24 channels are multiplexed per second, and the output is required to settle to 0.1% accuracy, the amplifier's bandwidth cannot be limited to less than 30Hz. Yet the noise contribution of the OP-27 will still be only $0.11\mu\text{Vp-p}$, which is equivalent to an error of only 0.02°C .

The ● denotes the specifications which apply over full operating temperature range.

Note 1: Input Offset Voltage measurements are performed by automatic test equipment approximately 0.5 seconds after application of power. A and E grades are guaranteed fully warmed up.

Note 2: Long Term Input Offset Voltage Stability refers to the average trend line of Offset Voltage vs Time over extended periods after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 days are typically $2.5\mu V$ —refer to typical performance curve.

Note 3: Sample tested. Contact factory for 100% testing of 10Hz voltage noise.

Note 4: Parameter is guaranteed by design and is not tested.

Note 5: See test circuit and frequency response curve for 0.1Hz to 10Hz tester in Applications Information section.

Note 6: See test circuit for current noise measurement in Applications Information section.

Note 7: The Average Input Offset Drift performance is within the specifications unnullled or when nullled with a pot having a range of $8k\Omega$ to $20k\Omega$.

Note 8: The OP-27/37's inputs are protected by back-to-back diodes. Current limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds $\pm 0.7V$, the input current should be limited to 25mA.

APPLICATIONS INFORMATION

General

The OP-27/37 series devices may be inserted directly into OP-07, OP-05, 725, and 5534 sockets with or without removal of external compensation or nulling components. In addition, the OP-27/37 may be fitted to 741 sockets with the removal or modification of external nulling components.

Noise Testing

The 0.1Hz to 10Hz peak-to-peak noise of the OP-27/OP-37 is measured in the test circuit shown. The frequency response of this noise tester indicates that the 0.1Hz corner is defined by only one zero. The test time to measure 0.1Hz to 10Hz noise should not exceed 10 seconds, as this time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1Hz.

Measuring the typical 80nV peak-to-peak noise performance of the OP-27/37 requires special test precautions:

- (a) The device should be warmed up for at least five minutes. As the op amp warms up, its offset voltage changes typically $4\mu\text{V}$ due to its chip temperature increasing 10°C to 20°C from the moment the power supplies are turned on. In the 10 second measurement interval these temperature-induced effects can easily exceed tens of nanovolts.

- (b) For similar reasons, the device must be well shielded from air currents to eliminate the possibility of thermoelectric effects in excess of a few nanovolts, which would invalidate the measurements.

- (c) Sudden motion in the vicinity of the device can also "feedthrough" to increase the observed noise.

A noise-voltage density test is recommended when measuring noise on a large number of units. A 10Hz noise-voltage density measurement will correlate well with a 0.1Hz to 10Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the $1/f$ corner frequency.

Current noise is measured and calculated by the following formula:

$$i_n = \frac{[e_{no}^2 - (130\text{nV})^2]^{1/2}}{1\text{M}\Omega \times 100}$$

0.1Hz to 10Hz Noise Test Circuit

0.1Hz to 10Hz p-p Noise Tester Frequency Response

APPLICATIONS INFORMATION

Offset Voltage Adjustment

The input offset voltage of the OP-27/37, and its drift with temperature, are permanently trimmed at wafer testing to a low level. However, if further adjustment of V_{OS} is necessary, the use of a 10k nulling potentiometer will not degrade drift with temperature. Trimming to a value other than zero creates a drift of $(V_{OS}/300) \mu V/^{\circ}C$, e.g., if V_{OS} is adjusted to $300 \mu V$, the change in drift will be $1 \mu V/^{\circ}C$.

Standard Adjustment

The adjustment range with a 10k pot is approximately $\pm 2.5mV$. If less adjustment range is needed, the sensitivity and resolution of the nulling can be improved by using a smaller pot in conjunction with fixed resistors. The example has an approximate null range of $\pm 200 \mu V$.

Improved Sensitivity Adjustment

Offset Voltage and Drift

Thermocouple effects, caused by temperature gradients across dissimilar metals at the contacts to the input terminals, can exceed the inherent drift of the amplifier unless proper care is exercised. Air currents should be minimized, package leads should be short, the two input leads should be close together and maintained at the same temperature.

The circuit shown to measure offset voltage is also used as the burn-in configuration for the OP-27/37, with the supply voltages increased to $\pm 20V$, $R_1=R_3=10k$, $R_2=200\Omega$, $A_V=100$.

Test Circuit for Offset Voltage and Offset Voltage Drift with Temperature

Unity Gain Buffer Applications (OP-27 Only)

When $R_f \leq 100\Omega$ and the input is driven with a fast, large signal pulse ($> 1V$), the output waveform will look as shown in the pulsed operation diagram.

During the fast feedthrough-like portion of the output, the input protection diodes effectively short the output to the input and a current, limited only by the output short circuit protection, will be drawn by the signal generator. With $R_f \geq 500\Omega$, the output is capable of handling the current requirements ($I_L \leq 20mA$ at $10V$) and the amplifier stays in its active mode and a smooth transition will occur.

As with all operational amplifiers when $R_f > 2k\Omega$, a pole will be created with R_f and the amplifier's input capacitance, creating additional phase shift and reducing the phase margin. A small capacitor (20pF to 50pF) in parallel with R_f will eliminate this problem.

Dual Matched Low Noise Precision Op Amp and Dual High Speed Low Noise Precision Op Amp

FEATURES

- Guaranteed $80\mu\text{V}$ Max. V_{OS}
- Guaranteed $6.0\text{nV}/\sqrt{\text{Hz}}$ 10Hz Voltage Noise Density
- Guaranteed $3.9\text{nV}/\sqrt{\text{Hz}}$ 1kHz Voltage Noise Density
- Guaranteed $1\mu\text{V}/^\circ\text{C}$ Max. V_{OS} Drift
- Guaranteed 1 Million Min. Voltage Gain
- Guaranteed Matching Characteristics
- Guaranteed $10\text{V}/\mu\text{s}$ Min. Slew Rate (OP-237)

APPLICATIONS

- Instrumentation Amplifiers
- Low Level Signal Processing
- Low Noise Audio Amplifiers
- Strain Gauge Amplifiers

DESCRIPTION

The OP-227 is a dual matched precision op amp which combines low offset, low noise, and high gain with excellent matching characteristics. Typical individual amplifier specifications of $20\mu\text{V}$ V_{OS} , $0.2\mu\text{V}/^\circ\text{C}$ drift, 10nA I_B and $2.8\text{nV}/\sqrt{\text{Hz}}$ 10Hz noise voltage density make the OP-227 an impressive performer in terms of single amplifiers. Matching characteristics are specified with guaranteed limits on all critical parameters including V_{OS} , V_{OS} drift, I_{BIAS} and CMRR (see the Features section), which make the OP-227 an ideal choice for two and three op amp instrumentation amplifier applications.

The OP-237 offers DC specifications identical to the OP-227 and is decompensated for higher speed operation at inverting gains greater than 5.

Precision Amplifier Drives 300Ω Load to $\pm 10\text{V}$ with 0.05% Accuracy

The ● denotes the specifications which apply over the full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

Note 1: Input offset voltage measurements are performed by automated test equipment approximately 0.5 seconds after application of power.

Note 2: Long-Term Input Offset Voltage Stability refers to the average trend line of V_{OS} vs Time over extended periods after the first 30 days of operation.

Note 3: Sample tested.

Note 4: Parameter is guaranteed by design.

Note 5: See test circuit and frequency response curve for 0.1Hz to 10Hz tester.

Note 6: See test circuit for current noise measurement.

Note 7: The input offset drift performance is within the specifications un-nulled or when nulled with $R_P = 8k\Omega$ to $20k\Omega$.

Note 8: The inputs are protected by back-to-back diodes. Current limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds $\pm 0.7V$, the input current should be limited to 25mA.

Note 9: The V^+ supply terminals are completely independent and may be powered by separate supplies if desired (this approach, however, would sacrifice the advantages of the power supply rejection ratio matching). The V^- supply terminals are both connected to the common substrate and must be tied to the same voltage. Both V^- pins should be used.

APPLICATIONS INFORMATION

Noise Testing

The 0.1Hz to 10Hz peak-to-peak noise of the OP-227/OP-237 is measured in the test circuit shown. The frequency response of this noise tester indicates that the 0.1Hz corner is defined by only one zero. The test time to measure 0.1Hz to 10Hz noise should not exceed 10 seconds, as this time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1Hz.

Measuring the typical 60nV peak-to-peak noise performance of the OP-227/OP-237 requires special test precautions:

- The device should be warmed up for at least five minutes. As the op amp warms up, its offset voltage changes typically $3\mu\text{V}$ due to its chip temperature increasing 10°C to 20°C from the moment the power supplies are turned on. In the 10 second measurement interval these temperature-induced effects can easily exceed tens of nanovolts.
- For similar reasons, the device must be well shielded from air currents to eliminate the possibility of thermoelectric effects in excess of a few nanovolts, which would invalidate the measurements.
- Sudden motion in the vicinity of the device can also "feed through" to increase the observed noise.

0.1Hz to 10Hz Noise Test Circuit

A noise-voltage density test is recommended when measuring noise on a large number of units. A 10Hz noise voltage density measurement will correlate well with a 0.1Hz to 10Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the $1/f$ corner frequency.

Current noise is measured in the circuit shown and calculated by the following formula:

$$i_n = \frac{[e_{no}^2 - (130\text{nV})^2]^{1/2}}{1\text{M}\Omega \times 100}$$

The OP-227/OP-237 achieves its low noise, in part, by operating the input stage at $120\mu\text{A}$ versus the typical $10\mu\text{A}$ of most other op amps. Voltage noise is inversely proportional, while current noise is directly proportional to the square root of the stage current. Therefore, the OP-227/OP-237 current noise will be relatively high. At low frequencies, the low $1/f$ current noise corner frequency ($\approx 120\text{Hz}$) minimizes current noise to some extent.

0.1Hz to 10Hz p-p Noise Tester Frequency Response

APPLICATIONS INFORMATION

In most practical applications, however, current noise will not limit system performance. This is illustrated in the total noise versus source resistance plot, where total noise = $[(\text{voltage noise})^2 + (\text{current noise} \times R_S)^2 + (\text{resistor noise})^2]^{1/2}$.

Three regions can be identified as a function of source resistance:

(i) $R_S \leq 400\Omega$ - Voltage noise dominates

(ii) $400\Omega \leq R_S \leq 50k\Omega$ at 1kHz Resistor noise dominates
 $400\Omega \leq R_S \leq 8k\Omega$ at 10Hz

(iii) $R_S > 50k\Omega$ at 1kHz Current noise dominates
 $R_S > 8k\Omega$ at 10Hz

Clearly the OP-227/OP-237 should not be used in region (iii), where total system noise is at least six times higher than the voltage noise of the op amp, i.e., the low voltage noise specification is completely wasted.

APPLICATIONS INFORMATION

OP AMP MATCHING

Advantages of Matched Dual Op Amps

In many applications the performance of a system depends on the matching between two operational amplifiers rather than the individual characteristics of the two op amps. Two or three op amp instrumentation amplifiers, tracking voltage references and low drift active filters are some of the circuits requiring matching between two op amps.

The well-known triple op amp configuration illustrates these concepts. Output offset is a function of the difference between the offsets of the two halves of the OP-227/OP-237. This error cancellation principle holds for a considerable number of input referred parameters in addition to offset voltage and its drift with temperature. Input bias current will be the average of the two non-inverting input currents (I_B^+). The difference between these two currents (I_{OS}^+) is the offset current of the instrumentation amplifier. The difference between the inverting input currents (I_{OS}^-) will cause errors flowing through R1, R2, and R3. Common mode and power supply rejections will be dependent only on the match between the two amplifiers (assuming perfect resistor matching).

The concepts of common mode and power supply rejection ratio match ($\Delta CMRR$ and $\Delta PSRR$) are best demonstrated with a numerical example:

Assume $CMRR_A = +1.0\mu V/V$ or 120dB,
 and $CMRR_B = +0.75\mu V/V$ or 122.5dB,
 then $\Delta CMRR = 0.25\mu V/V$ or 132dB;
 if $CMRR_B = -0.75\mu V/V$ which is still 122.5dB,
 then $\Delta CMRR = 1.75\mu V/V$ or 115dB.

Clearly, the OP-227/OP-237, by specifying and guaranteeing all of these matching parameters, can significantly improve the performance of matching dependent circuits.

Three Op Amp Instrumentation Amplifier

Trim R8 for gain

Trim R9 for DC common mode rejection

Trim R10 for AC common mode rejection

Typical performance of the instrumentation amplifier:

Input offset voltage = $60\mu V$

Input bias current = $\pm 15nA$

Input offset current = $\pm 20nA$

Input noise = $0.08\mu Vp-p$

Power bandwidth ($V_O = \pm 10V$) = 250kHz

APPLICATIONS INFORMATION

Two Op Amp Instrumentation Amplifier

*TRIM FOR COMMON MODE REJECTION
†TRIM FOR GAIN

$$\text{GAIN} = \frac{R_4}{R_3} \left[1 + \frac{1}{2} \left(\frac{R_2}{R_1} + \frac{R_3}{R_4} \right) + \frac{R_2 + R_3}{R_5} \right] \approx 100$$

5 Volt, 5 Amp Voltage Regulator

FEATURES

- *Guaranteed* 2% Initial Tolerance of output voltage
- 5 Amp Output Current
- 40 Watt Capability
- Full Internal Overload Protection
- 100% Burn-in in Thermal Limit

APPLICATIONS

- Local 5V Regulators
- On Card Regulation
- Lab Supplies
- Instrumentation Supplies

DESCRIPTION

The LT1003 is a 5 amp version of the popular LM123 5V regulator. In addition to higher output current, it offers improved line regulation and an initial output voltage tolerance of $\pm 2\%$. These tightened specifications ease design and application problems several ways: safety margin is improved, error budgets on other parts of the system are expanded, and output voltage loss due to long supply runs can be better tolerated.

The LT1003 incorporates Linear Technology's advanced design, process and test techniques for improved quality and reliability over similar device types. Specifically, all devices are burned in by shorting the outputs, thereby forcing the regulator into its current limit and eventually, thermal limit mode. This ensures that all device protection features are working.

Standard 5 Volt Regulator

Load Regulation *

* The LT1003 has load compensation to cancel the effects of voltage loss in the output lead. This results in a nominal "zero" load regulation. The shaded band shows typical production spread.

ABSOLUTE MAXIMUM RATINGS

Input Voltage 20 Volts
 Power Dissipation Internally Limited
 Operating Junction Temperature Range
 LT1003M -55°C to 150°C
 LT1003C 0°C to 125°C

TYPICAL APPLICATIONS

Crowbar Protection††

* THE 6.4V ZENER IS INTERNAL TO THE LT1003.

** Q1 MUST BE ABLE TO WITHSTAND CONTINUOUS CURRENTS OF 8A IF ADDITIONAL SYSTEM SHUTDOWN IS NOT USED.

† Q2 MUST WITHSTAND LARGE SURGE CURRENTS UNTIL THE 8A FUSE BLOWS. PEAK SURGE CURRENT IS LIMITED ONLY BY FUSE, WIRING, AND FILTER CAP RESISTANCE.

†† TRIP POINT IS APPROXIMATELY 7.3V.

Bypass Capacitors

The LT1003 does not require an output capacitor for resistive loads. For almost all applications, however, a $1\mu\text{F}$ or larger solid tantalum capacitor is used on the output within 2" of the regulator. This greatly improves the output impedance of the regulator at high frequencies. For critical applications where very low impedance is required at high frequencies, a $10\mu\text{F}$ solid tantalum output capacitor is recommended. Total output capacitance may be increased without limit, either local or distributed.

A $2\mu\text{F}$ or larger input capacitor (solid tantalum) must be added if the regulator is more than 4" away from the large filter capacitor in the input supply. A $25\mu\text{F}$ aluminum capacitor may be substituted for the tantalum unit.

Avoiding Ground Loops

For best regulation, the ground pin of the LT1003 should be tied directly to the load point as shown below. This prevents excess drop in load voltage caused by load current flowing through the ground return lead. This is essentially a Kelvin connection for the

low side of the regulator. A Kelvin connection cannot be made for the high output of the regulator because only three pins are available on the package. Therefore, every attempt should be made to minimize the resistance between the output pin of the regulator and the load. #18 gauge hookup wire has a resistance of 0.006 ohms per foot. This translates to 0.6% change in load voltage at full load current. The LT1003 is specified at 2% maximum load regulation, so one foot of wire represents a significant loss of regulation. If connectors are used, careful consideration must be given to contact resistance, especially if the connector is subjected to nasty ambients, vibration, or multiple insertions.

TYPICAL APPLICATIONS

Raw Supply

Transformer, diode, and capacitor selection for the raw supply to the LT1003 is very important because of the conflicting requirements for reliability, efficiency, and resistance to "brown-out" conditions. High secondary voltage on the transformer will cause unnecessarily high power dissipation in the regulator. Too low a secondary voltage will cause the regulator output to drop out of regulation with only a small reduction in AC mains voltage. The following formula gives a good starting point for transformer selection. This formula assumes a full-wave center tapped transformer, using two rectifier diodes.

$$V_{RMS} = \left(\frac{V_{OUT} + V_{DO} + V_{RECT} + V_{RIP}}{\sqrt{2}} \right) \left(\frac{V_{NOM}}{V_{LOW}} \right) (1.1^*)$$

(secondary
each side)

$$I_{RMS} = (I_{OUT}) (1.2)$$

where:

$$V_{OUT} = 5V$$

$$V_{DO} = \text{Minimum input-output differential of the regulator}$$

*1.1 is a nominal load regulation factor for the transformer

$$V_{RECT} = \text{Rectifier forward drop at } 3I_{OUT}$$

$$V_{RIP} = \frac{1}{2} \text{ p-p capacitor ripple voltage}$$

$$V_{RIP} \approx \frac{(5.3 \times 10^{-3}) (I_{OUT})}{2C}$$

$$V_{NOM} = \text{Rated line voltage for the transformer (RMS)}$$

$$V_{LOW} = \text{Lowest expected line voltage (RMS)}$$

$$I_{OUT} = \text{DC output current}$$

Example: $I_{OUT} = 4A$, $V_{OUT} = 5V$

Assume: $V_{DO} = 2.5V$, $V_{RECT} = 1.1V$, $C = 12,000\mu F$
 $V_{NOM} = 115V$, $V_{LOW} = 105V$

$$V_{RIP} = \frac{(5.3 \times 10^{-3}) (4)}{2 (12 \times 10^{-3})} = 0.88V$$

$$V_{RMS} = \left(\frac{5 + 2.5 + 1.1 + 0.88}{\sqrt{2}} \right) \left(\frac{115}{105} \right) (1.1)$$

$$= 8.08 V_{RMS}$$

The filter capacitor should be at least $2000\mu F$ per amp of load current to minimize capacitor heating and ripple voltage. The diodes should be rated at 8–10 amps even though their average current is only 2.5A at full rated load current. The reason for this is that although the *average* current is 2.5A, the RMS current is typically twice this value. In addition, the diode must withstand very high surge currents during power turn-on. This surge can be 10–20 times the DC rating of the supply, depending on capacitor size and wiring resistance and inductance.

FEATURES

- Two Regulated Outputs
 - +5V at 1 amp
 - +5V at 35mA
- 2% Output Voltage Tolerance
- 66 dB Ripple Rejection
- 0.5% Load Regulation
- TTL and CMOS Compatible Logic Control
- 100% Thermal Burn-in On All Devices

APPLICATIONS

- Power Supply Sequencing
- Remote On/Off Power Control
- Selective System Power During Emergency Power Operation
- Memory Power Supply With Back-Up

DESCRIPTION

The LT1005 features two positive 5 volt regulators in the same package. The main regulator offers excellent performance while supplying load currents up to 1 amp, and the auxiliary regulator provides similar performance while supplying lighter loads of 35mA. The main regulator has the additional feature of being under the shutdown control of a logic signal. When the enable pin is taken to a low logic level, the main regulator shuts down and its output voltage goes to near zero volts. During this command, the auxiliary output is unaffected by the main regulator's condition and continues to provide a 5 volt output.

The main output has current and power limiting combined with thermal shutdown to make it virtually blow-out proof. The auxiliary output is not affected by the thermal shutdown mechanism or the state of the main output, allowing it to be used as a back-up in case of overloads or shorts on the main supply.

The logic input of the LT1005 (enable pin) has a 1.6V threshold and can be driven from a high source impedance. This allows it to be driven by most logic families, including TTL & CMOS.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Unless otherwise indicated, these specifications apply for $V_{IN} = 10\text{V}$, $I_O = 0\text{mA}$, and $T_J = 25^\circ\text{C}$.

Note 2: Line and load regulation are measured using a low duty cycle pulse, causing little change in the junction temperature. Effects due to thermal gradients and device heating must be taken into account separately.

Note 3: When the enable pin is at a low logic level, current flows out of the enable pin.

Note 4: Pulse length for this measurement is 20msec.

Note 5: Input Voltage is reduced until output drops by 100mV from its initial value.

APPLICATIONS INFORMATION

General Information

The LT1005 is a dual output 5V regulator. The main output is capable of delivering up to 1 amp of load current and can be shut down with a logic signal. The auxiliary output supplies a minimum of 35mA and is unaffected by the logic signal. The outputs are trimmed to $\pm 2\%$ initial tolerance and exhibit excellent line and load regulation.

The logic control feature makes the LT1005 ideal for many system applications where it is desirable to power up a portion of the system for a period of time and then power the system down during a standby operation. As an example, the LT1005 could be used to activate various memory space locations only as needed, thus saving substantial power dissipation and other cooling costs. The LT1005 could also be used to power micro-computers, such as the 8048 series. The auxiliary supply can be used for RAM keep-alive during power down operation. Additional power savings can be accomplished by using the LT1005 to power PROM, EPROM, and E²PROM devices. During program load, or look-up table operations the ROM type device can be activated and its' contents placed in RAM, and then the ROM power can be removed. Or for high speed but low power data acquisition systems, the power could be applied to fast memory, then the data transferred to CMOS memory. The main regulator can then be shutdown and the CMOS memory can be powered by the auxiliary for lower power dissipation. Other applications, such as multiple power supply sequencing, elimination of expensive AC and DC power switches, delayed start applications, switching 5V DC loads, and many others are now easily accomplished.

Timing functions can also be performed directly at the enable pin, such as delayed power-up or power-down.

Because a logic low on the enable pin shuts down the main regulator, feedback from output to enable can be used to generate hysteresis or latching functions.

The low quiescent current drain of the LT1005 makes it useful in battery powered or battery back-up appli-

cations. The enable pin can be used as a "low battery" detector or to shut down major portions of system power, allowing memory portions to continue to operate from the auxiliary output. At low output currents, the auxiliary output will regulate with input voltage typically as low as 6.1V, giving maximum battery life.

Good design practice with all regulators is to bypass the input and output terminals. A $1\mu\text{F}$ solid tantalum at the input and at both outputs is suggested. For the applications which follow, the bypass capacitors are still recommended, but are not shown on the diagram for simplicity. It is also recommended that for maximum noise immunity, the voltage enable pin be tied high if it is unused. It can be tied directly to V_{IN} as shown in Figure 1, or to the auxiliary output. If the enable pin is left open, it will float to a high logic level of approximately 1.6V and the main output regulator will be at 5V.

Figure 1.

The enable pin is fully protected against input voltages up to 20 volts, even if the power input voltage is zero.

The basic shutdown control circuit uses a direct gate drive or an open collector driver and a pull-up resistor which is tied to V_{AUX} as shown in Figure 2.

Figure 2.

Driving the Enable Pin

The enable pin equivalent schematic is shown in Fig. 3, with V/I characteristics shown in Fig. 4. Basically, enable pin current is zero above the threshold, and between 2 and 70 μ A below the threshold, flowing out of the pin. Standard logic, such as TTL & CMOS will interface directly to the enable pin, even if the logic output swing is higher than the input voltage (V_{IN}) to the regulator. 15V CMOS can be used to drive the enable pin even if the regulator is not powered up, without loading the CMOS output.

Timing functions, such as delayed power-up or power-down can be implemented by driving the enable pin with an RC network. The current flowing out of the enable pin should not be used as the timing current in delayed power up applications, as it is temperature sensitive and varies somewhat from device to device. Instead, a resistor tied to the auxiliary output, the input, or to a logic signal should be used. The timing resistor chosen should provide at least 500 μ A of current to "swamp-out" the effects of the internal current.

Main Output Current/Voltage Characteristics

Following a high to low transition at the enable pin, the main regulator output will begin to drop after a delay of approximately 1 μ sec. With no capacitive load, the output will fall to zero in approximately 0.5 μ sec ($R_L = 5-100\Omega$). With a capacitive load, fall time is limited by the RC product of the load and the output capacitance. For light loads ($R_L > 100\Omega$), the discharge time is controlled by an internal equivalent load of 200 Ω for output voltages down to 1 volt. Below 1 volt, the output decays linearly, with a slope equivalent to the load capacitance and a pull down current of approximately 0.5mA. The DC output voltage in the shutdown mode is approximately 0.1 volt for input voltages (V_{IN}) up to

15V. If V_{IN} is 20V, the output during shutdown will be approximately 0.2V due to an internal current path in the regulator.

Figure 4.

The user should note that the output in the low state can only sink about 0.5mA. If current is forced into the output, the output voltage will rise to 0.8V at 1mA and above 1V at 10mA. With no output capacitor, the rise time of the main output is about 1.5 μ s. With an output capacitor, rise time is limited by the short circuit current of the LT1005 and the load capacitance; $t_r \approx (C)(5V)/(1.5A)$. A 1 μ F output capacitor slows the output rise time to approximately 3 μ s and a 10 μ F output capacitor slows the output rise time to 30 μ s.

Output Current

The main output current limits at about 1.7A for input voltages below 19V. Internal foldback, or "power limiting" circuitry detects the input-output voltage differential and reduces current limit for input to output voltages exceeding 14V. With 20V input, for instance, short circuit current is reduced to $\approx 1.1A$.

An additional feature of the LT1005 is that the auxiliary supply does not incorporate nor is it affected by thermal shutdown. Any fault condition of the main regulator will not affect the auxiliary output voltage.

The following applications circuits will serve to indicate the versatility of the LT1005.

TYPICAL APPLICATIONS

First-On, Last-Off Sequencing

First-On, First-Off Sequencing

Power Supply Turn-On Sequencing

Fast Turn-Off, Delayed Turn-On

Thermal Cutoff at High Ambient Temperature

Latch-Off for $V_{OUT} \leq 4.7\text{V}$

Proportional Motor Speed Controller

TRANSFORMER AND RECTIFIER SET
 $V_N = 9V$ DC NOMINAL

The circuit diagram shows an LT1005 IC with the following connections:

- IN:** Connected to the +9V DC nominal supply.
- OUT:** Connected to the +5V supply.
- EN:** Connected to the junction of resistors R_1 (7.5k) and R_2 (3.6k).
- GND:** Connected to ground.
- AUX:** Connected to the +5V supply.

The input signal to the EN pin is derived from a transformer and rectifier set. The input voltage is $V_N = 9V$ DC NOMINAL. The circuit includes a diode (IN4148) and a resistor ($R_3 = 4.7k$) connected to ground.

The shutdown voltage is calculated as:

$$V_{shutoff} (INPUT) \approx (3.8V) \left(\frac{R_2 + R_1}{R_2} \right)$$

OUTPUT SHUTS OFF WHEN 110V AC TRANSFORMER IS OVER VOLTAGED TO 220 VAC.

Diagram illustrating the connection of the LT1005 optocoupler. The chip has pins IN, OUT, EN, GND, and AUX. The circuit shows the following connections:

- IN is connected to V_{IN} .
- OUT is connected to +5V.
- EN is connected to a resistor R, which is then connected to GND.
- GND is connected to the common ground.
- AUX is connected to +5V.

The internal circuit of the optocoupler is shown, including a transistor and a diode. The text indicates that the output is "ON" when the coupler is "ON".

SELECT R DEPENDING UPON THE ON-RESISTANCE OF THE OPTO COUPLER

IF C_2 IS LARGER THAN $10\mu\text{F}$, C_1 SHOULD BE INCREASED TO $C_2/10$

Diagram of the LT1005 monostable multivibrator circuit. The circuit includes a capacitor C_1 and a resistor R_1 (3.9k) connected to the EN pin. The output OUT is connected to +5V. The formula for the delay is given as $t_{\text{DELAY}} \approx 0.4 R_1 C_1$.

TYPICAL APPLICATIONS

Fast Electronic Circuit Breaker

Battery Voltage Sensing Circuit

Memory Save-on-Power-Down

The auxiliary output powers the memory, while the main output powers the system and is connected to the memory store pin. When power goes down, the main output goes low, commanding the memory to store. The auxiliary output then drops out.

3A. Negative Adjustable Regulator

FEATURES

- *Guaranteed* 1% Initial Voltage Tolerance
- *Guaranteed* 0.015%/V Line Regulation
- *Guaranteed* 0.02%/W Thermal Regulation
- 100% Burn-in in Thermal Limit

APPLICATIONS

- Adjustable Power Supplies
- System Power Supplies
- Precision Voltage/Current Regulators
- On-Card Regulators

DESCRIPTION

The LT1033 negative adjustable regulator will deliver up to 3 Amps output current over an output voltage range of -1.2V to -32V . Linear Technology has made significant improvements in these regulators compared to previous devices, such as better line and load regulation, and a maximum output voltage error of 1%.

The LT1033 is easy to use and difficult to damage. Internal current and power limiting as well as true thermal limiting prevents device damage due to overloads or shorts, even if the regulator is not fastened to a heat sink.

Maximum reliability is attained with Linear Technology's advanced processing techniques combined with a 100% burn-in in the thermal limit mode. This assures that all device protection circuits are working and eliminates field failures experienced with other regulators that receive only standard electrical testing.

Guaranteed Minimum Output Current

Adjustment Current

APPLICATION INFORMATION

Output Voltage: The output voltage is determined by two external resistors, R_1 & R_2 (see Figure 1). The exact formula for the output voltage is:

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} (R_2)$$

Where: V_{REF} = Reference Voltage, I_{ADJ} = Adjustment Pin Current. In most applications, the second term is small enough to be ignored, typically about 0.5% of V_{OUT} . In more critical applications, the exact formula should be used, with I_{ADJ} equal to $65\mu A$. Solving for R_2 yields:

$$R_2 = \frac{V_{OUT} - V_{REF}}{\frac{V_{REF}}{R_1} - I_{ADJ}}$$

Smaller values of R_1 and R_2 will reduce the influence of I_{ADJ} on the output voltage, but the no-load current drain on the regulator will be increased. Typical values for R_1 are between 100Ω and 300Ω , giving 12.5mA and 4.2mA no-load current respectively. There is an additional consideration in selecting R_1 , the minimum load current specification of the regulator. The operating current of the LT1033 flows from input to output. If this current is not absorbed by the load, the output of the regulator will rise above the regulated value. The current drawn by R_1 and R_2 is normally high enough to

absorb the current, but care must be taken in no-load situations where R_1 and R_2 have high values. The maximum value for the operating current, which must be absorbed, is 5mA for the LT1033. If input-output voltage differential is less than 10V, the operating current that must be absorbed drops to 3mA.

Figure 1

EXAMPLE:

1. A precision 10V regulator to supply up to 3 Amp load current.

a. Select $R_1 = 100\Omega$ to minimize effect of I_{ADJ}

b. Calculate $R_2 = \frac{V_{OUT} - V_{REF}}{\frac{V_{REF}}{R_1} - I_{ADJ}} = \frac{10V - 1.25V}{\frac{1.25V}{100\Omega} - 65\mu A} = 704\Omega$

APPLICATION INFORMATION

Capacitors and Protection Diodes: An output capacitor, C3, is required to provide proper frequency compensation of the regulator feedback loop. A $2\mu\text{F}$ or larger solid tantalum capacitor is generally sufficient for this purpose if the 1MHz impedance of the capacitor is 1Ω or less. High Q capacitors, such as Mylar, are not recommended because they tend to reduce the phase margin at light load currents. Aluminum electrolytic capacitors may also be used, but the minimum value should be $25\mu\text{F}$ to ensure a low impedance at 1MHz. The output capacitor should be located within a few inches of the regulator to keep lead impedance to a minimum. The following caution should be noted: if the output voltage is greater than 6V and an output capacitor greater than $20\mu\text{F}$ has been used, it is possible to damage the regulator if the input voltage becomes shorted, due to the output capacitor discharging into the regulator. This can be prevented by using diode D1 (see Figure 2) between the input and the output.

The input capacitor, C2, is only required if the regulator is more than 4 inches from the raw supply filter capacitor.

Bypassing the Adjustment Pin: The adjustment pin of the LT1033 may be bypassed with a capacitor to ground, C1, to reduce output ripple, noise, and impedance. These parameters scale directly with output voltage if the adjustment pin is not bypassed. A bypass capacitor reduces ripple, noise, and impedance to that of a 1.25V regulator. In a 15V regulator for example, these parameters are improved by $15\text{V}/1.25\text{V} = 12$ to 1. This improvement holds only for those frequencies where the impedance of the bypass capacitor is less than R_1 . Ten microfarads is generally sufficient for 60Hz power line applications where the ripple frequency is 120Hz, since $X_C = 130\Omega$. The capacitor should have a voltage rating at least as high as the output voltage of the regulator. Values larger than $10\mu\text{F}$ may be used, but if the output is larger than 25V, a diode, D2, should be added between the output and adjustment pins (see Figure 2).

* D1 protects the regulator from input shorts to ground. It is required only when C3 is larger than $20\mu\text{F}$ and V_{OUT} is larger than 6V.

** D2 protects the adjust pin of the regulator from output shorts if C2 is larger than $10\mu\text{F}$ and V_{OUT} is larger than $\sim 25\text{V}$.

Figure 2

Proper Connection of Divider Resistors: The LT1033 has a load regulation specification of 0.8% and is measured at a point 1/8" from the bottom of the package. To prevent degradation of load regulation, the resistors which set output voltage, R1 and R2, must be connected as shown in Figure 3. Note that the positive side of the load has a true force and sense (Kelvin) connection, but the negative side of the load does not.

Figure 3

R1 should be connected *directly* to the output lead of the regulator, as close as possible to the specified point 1/8" from the case. R2 should be connected to the positive side of the load separately from the positive (ground) connection to the raw supply. With this arrangement, load regulation is degraded only by the resistance between the regulator output pin and the load. If R1 is connected to the load, regulation will be degraded.

TYPICAL APPLICATIONS

The output stability, load regulation, line regulation, thermal regulation, temperature drift, long term drift, and noise, can be improved by a factor of 6.6 over the standard regulator configuration. This assumes a zener whose drift and noise is considerably better than the regulator itself. The LM329B has 20PPM/°C maximum drift and about 10 times lower noise than the regulator.

In the application shown below, regulators #2 to "N" will track regulator #1 to within $\pm 24\text{mV}$ initially, and to $\pm 60\text{mV}$ over all load, line, and temperature conditions. If any regulator output is shorted to ground, all other outputs will drop to $\approx -2\text{V}$. Load regulation of regulators 2 to "N" will be improved by $V_{\text{OUT}}/1.25\text{V}$ compared to a standard regulator, so regulator #1 should be the one which has the lowest load current.

Multiple Tracking Regulators

High Stability Regulator

Dual Tracking 3A Supply $\pm 1.25\text{V}$ to $\pm 20\text{V}$

- Memory Power Supply with Back-Up

DESCRIPTION

The LT1035 features two positive 5V regulators in the same package. The main regulator offers excellent performance while supplying load currents up to 3A, and the auxiliary regulator provides similar performance while supplying lighter loads of 75mA. The main regulator has the additional feature of being under the shutdown control of a logic signal. When the enable pin is taken to a low logic level, the main regulator shuts down and its output voltage goes to near 0V. During this command, the auxiliary output is unaffected by the main regulator's condition and continues to provide a 5V output.

The main output has current and power limiting combined with thermal shutdown to make it virtually blowout proof. The auxiliary output is not affected by the thermal shutdown mechanism or the state of the main output, allowing it to be used as a back-up in case of overloads or shorts on the main supply.

The logic input of the LT1035 (enable pin) has a 1.6V threshold and can be driven from a high source impedance. This allows it to be driven by most logic families, including TTL and CMOS.

For a 1A version of the LT1035, please see the LT1005 data sheet. For a 12V output voltage version, consult the factory.

APPLICATIONS INFORMATION

General Information

The LT1035 is a dual output 5V regulator. The main output is capable of delivering up to 3A of load current and can be shut down with a logic signal. The auxiliary output supplies a minimum of 75mA and is unaffected by the logic signal. The outputs are trimmed to $\pm 2\%$ initial tolerance and exhibit excellent line and load regulation.

The logic control feature makes the LT1035 ideal for many system applications where it is desirable to power-up a portion of the system for a period of time, and then power the system down during a standby operation. As an example, the LT1035 could be used to activate various memory space locations only as needed, thus saving substantial power dissipation and other cooling costs. The LT1035 could also be used to power microcomputers such as the 8048 series. The auxiliary supply can be used for RAM keep-alive during power-down operation. Additional power savings can be accomplished by using the LT1035 to power PROM, EPROM, and E²PROM devices. During program load or look-up table operations, the ROM type device can be activated and its contents placed in RAM, and then the ROM power can be removed. Or for high speed but low power data acquisition systems, the power could be applied to fast memory, then the data transferred to CMOS memory. The main regulator can then be shut down and the CMOS memory can be powered by the auxiliary for lower power dissipation. Other applications such as multiple power supply sequencing, elimination of expensive AC and DC power switches, delayed start applications, switching 5V DC loads, and many others are now easily accomplished.

Timing functions, such as delayed power-up or power-down, can also be performed directly at the enable pin.

Because a logic low on the enable pin shuts down the main regulator, feedback from output to enable can be used to generate hysteresis or latching functions.

The low quiescent current drain of the LT1035 makes it useful in battery-powered or battery back-up applications. The enable pin can be used as a "low battery" detector or to shut down major portions of system power,

allowing memory portions to continue to operate from the auxiliary output. At low output currents, the auxiliary output will regulate with input voltage typically as low as 6.1V, giving maximum battery life.

Good design practice with all regulators is to bypass the input and output terminals. A $2\mu\text{F}$ solid tantalum at the input and at both outputs is suggested. For the applications which follow, the bypass capacitors are still recommended, but for simplicity are not shown on the diagram. It is also recommended that for maximum noise immunity the voltage enable pin be tied high if it is unused. It can be tied directly to V_{IN} , as shown in Figure 1, or to the auxiliary output. If the enable pin is left open, it will float to a high logic level of approximately 1.6V and the main output regulator will be at 5V.

Figure 1

The enable pin is fully protected against input voltages up to 20V, even if the power input voltage is zero.

The basic shutdown control circuit uses a direct gate drive or an open collector driver and a pull-up resistor which are tied to V_{AUX} , as shown in Figure 2.

Figure 2

APPLICATIONS INFORMATION

Driving the Enable Pin

The enable pin equivalent schematic is shown in Figure 3. Basically, enable pin current is zero above the threshold and about $1.5\mu\text{A}$ below the threshold, flowing out of the pin. Standard logic, such as TTL and CMOS, will interface directly to the enable pin, even if the logic output swing is higher than the input voltage (V_{IN}) to the regulator. 15V CMOS can be used to drive the enable pin, even if the regulator is not powered up, without loading the CMOS output.

Figure 3

Timing functions, such as delayed power-up or power-down, can be implemented by driving the enable pin with an RC network. The current flowing out of the enable pin should not be used as the timing current in delayed power-up applications as it is temperature sensitive and varies somewhat from device to device. Instead, a resistor tied to the auxiliary output, the input, or to a logic signal should be used. The timing resistor chosen should provide at least $25\mu\text{A}$ of current to "swamp out" the effects of the internal current.

Main Output Current/Voltage Characteristics

Following a high to low transition at the enable pin, the main regulator output will begin to drop after a delay of approximately $0.4\mu\text{s}$. With no capacitive load, the output will fall to zero in approximately $0.8\mu\text{s}$ ($R_L = 2\Omega - 100\Omega$). With a capacitive load, fall time is limited by the RC product of the load and the output capacitance. For light loads ($R_L > 400\Omega$), the discharge time is controlled by an internal current pull-down of 15mA for output voltages down to 1.5V . Below 1.5V , the pull-down current drops to $\approx 4\text{mA}$. The DC output voltage in the shutdown mode is approximately 0.07V for input voltages (V_{IN}) up to 12V . If V_{IN} is 20V , the output during shutdown will be approximately 0.15V due to an internal current path in the regulator.

Output Characteristics in Low State

Figure 4

The user should note that the output in the low state can only sink about 3mA . If current is forced into the output, the output voltage will rise to 1V at 5mA and about 1.5V at 10mA . With no output capacitor, the rise time of the main output is about $3\mu\text{s}$. With an output capacitor, rise time is limited by the short circuit current of the LT1035 and the load capacitance; $t_r \approx (C)(5\text{V})/4\text{A}$. A $10\mu\text{F}$ output capacitor slows the output rise time to approximately $12\mu\text{s}$.

Output Current

The main output current limits at about 4A for input voltages below 12.5V . Internal foldback, or "power limiting", circuitry detects the input-output voltage differential and reduces current limit for input to output voltages exceeding 7.5V . With 20V input, for instance, short circuit current is reduced to $\approx 2.4\text{A}$.

An additional feature of the LT1035 is that the auxiliary supply does not incorporate, nor is it affected by, thermal shutdown. Any fault condition of the main regulator will not affect the auxiliary output voltage.

The following applications circuits will serve to indicate the versatility of the LT1035.

PACKAGE DESCRIPTION

T0-220 Package (5 Lead)

	T_{JMAX}	θ_{JC}
LT1035C	125°C	3°C/W

4-Pin Metal Package Similar to JEDEC TO-3

	T_{JMAX}	θ_{JC}
LT1035M	150°C	2.5°C/W
LT1035C	125°C	2.5°C/W

FEATURES

- Two Regulated Outputs
 - + 12V at 3A
 - + 5V at 75mA
- 2% Output Voltage Tolerance
- 60dB Ripple Rejection
- 0.7% Load Regulation
- TTL and CMOS Compatible Logic Control
- 100% Thermal Burn-In on All Devices

APPLICATIONS

- Power Supply Sequencing
- Remote On/Off Power Control
- Selective System Power during Emergency Power Operation
- Power Supply with Back-Up

DESCRIPTION

The LT1036 features two positive regulators in the same package. The 12V main regulator offers excellent performance while supplying load currents up to 3A, and the 5V auxiliary regulator provides similar performance while supplying lighter loads of 75mA. The main regulator has the additional feature of being under the shutdown control of a logic signal. When the enable pin is taken to a low logic level, the main regulator shuts down and its output voltage goes to near 0V. During this command, the auxiliary output is unaffected by the main regulator's condition and continues to provide a 5V output.

The main output has current and power limiting combined with thermal shutdown to make it virtually blowout proof. The auxiliary output is not affected by the thermal shutdown mechanism or the state of the main output, allowing it to be used as a back-up in case of overloads or shorts on the main supply.

The logic input of the LT1036 (enable pin) has a 1.6V threshold and can be driven from a high source impedance. This allows it to be driven by most logic families, including TTL and CMOS.

For a dual 5V version of the LT1036, please see the LT1035 data sheet.

APPLICATIONS INFORMATION

General Information

The LT1036 is a dual output regulator. The main 12V output is capable of delivering up to 3A of load current and can be shut down with a logic signal. The auxiliary 5V output supplies a minimum of 75mA and is unaffected by the logic signal. The outputs are trimmed to $\pm 2\%$ initial tolerance and exhibit excellent line and load regulation.

The logic control feature makes the LT1036 ideal for many system applications where it is desirable to power-up a portion of the system for a period of time, and then power the system down during a standby operation. Applications such as multiple power supply sequencing, elimination of expensive AC and DC power switches, delayed start applications, switching 12V DC loads, and many others are now easily accomplished.

Timing functions, such as delayed power-up or power-down, can also be performed directly at the enable pin.

Because a logic low on the enable pin shuts down the main regulator, feedback from output to enable can be used to generate hysteresis or latching functions.

The low quiescent current drain of the LT1036 makes it useful in battery-powered or battery back-up applications. The enable pin can be used as a "low battery" detector or to shut down major portions of system power, allowing memory portions to continue to operate from the auxiliary output. At low output currents, the auxiliary output will regulate with input voltage typically as low as 6.2V, giving maximum battery life.

Good design practice with all regulators is to bypass the input and output terminals. A $2\mu\text{F}$ solid tantalum at the input and at both outputs is suggested. For the applications which follow, the bypass capacitors are still recommended, but for simplicity are not shown on the diagram. It is also recommended that for maximum noise immunity the voltage enable pin be tied high if it is unused. It can be tied directly to V_{IN} , as shown in Figure 1, or to the auxiliary output. If the enable pin is left open, it will float to a high logic level of approximately 1.6V and the main output regulator will be at 12V.

The enable pin is fully protected against input voltages up to 30V, even if the power input voltage is zero.

The basic shutdown control circuit uses a direct gate drive or an open collector driver and a pull-up resistor which are tied to V_{AUX} , as shown in Figure 2.

Figure 1

Figure 2

Driving the Enable Pin

The enable pin equivalent schematic is shown in Figure 3. Basically, enable pin current is zero above the threshold and about $1.5\mu\text{A}$ below the threshold, flowing out of the pin. Standard logic, such as TTL and CMOS, will interface directly to the enable pin, even if the logic output swing is higher than the input voltage (V_{IN}) to the regulator. 15V CMOS can be used to drive the enable pin, even if the regulator is not powered up, without loading the CMOS output.

Figure 3

Timing functions, such as delayed power-up or power-down, can be implemented by driving the enable pin with an RC network. The current flowing out of the enable pin should not be used as the timing current in delayed power-up applications as it is temperature sensitive and varies somewhat from device to device. Instead, a resistor tied to the auxiliary output, the input, or to a logic signal

APPLICATIONS INFORMATION

should be used. The timing resistor chosen should provide at least $25\mu\text{A}$ of current to "swamp out" the effects of the internal current.

Main Output Current/Voltage Characteristics

Following a high to low transition at the enable pin, the main regulator output will begin to drop after a delay of approximately $0.4\mu\text{s}$. With no capacitive load, the output will fall to zero in approximately $0.8\mu\text{s}$ ($R_L = 4\Omega$ to 100Ω). With a capacitive load, fall time is limited by the RC product of the load and the output capacitance. For light loads ($R_L > 400\Omega$), the discharge time is controlled by an internal current pull-down of 15mA for output voltages down to 1.5V . Below 1.5V , the pull-down current drops to $\approx 4\text{mA}$. The DC output voltage in the shutdown mode is approximately 0.12V due to an internal current path in the regulator. (See Figure 4)

The user should note that the output in the low state can only sink about 3mA . If current is forced into the output, the output voltage will rise to 1V at 5mA and about 1.5V at 10mA . With no output capacitor, the rise time of the main output is about $12\mu\text{s}$. With an output capacitor, rise time is limited by the short circuit current of the LT1036 and the load capacitance. A $10\mu\text{F}$ output capacitor slows the output rise time to approximately $80\mu\text{s}$.

Output Current

The main output current limits at about 4A for input voltages below 20V . Internal foldback, or "power limiting", circuitry detects the input-output voltage differential and reduces current limit for input to output voltages exceeding 8V . With 25V input, for instance, short circuit current is reduced to $\approx 0.9\text{A}$.

An additional feature of the LT1036 is that the auxiliary supply does not incorporate, nor is it affected by, thermal shutdown. Any fault condition of the main regulator will not affect the auxiliary output voltage.

The following applications circuits will serve to indicate the versatility of the LT1036.

- High Power Linear Regulator
- Battery Chargers
- Power Driver
- Constant Current Regulator

DESCRIPTION

The LT1038 is a three terminal regulator which is capable of providing in excess of 10 amps output current over 1.2V to 32V range. The device is packaged in a standard TO-3 power package, and is plug-in compatible with industry standard adjustable regulators, such as the LM117 and LM138. Also, the LT1038 is a functional replacement for the LM396.

In addition to excellent load and line regulations, the LT1038 is fully protected by current limiting, safe area protection and thermal shutdown. New current limiting circuitry allows transient load currents up to 24 amps to be supplied for 500 μ s without causing the regulator to current limit and drop out of regulation during the transient.

On-chip trimming of initial reference voltage to $\pm 0.8\%$ combined with 0.4% load regulation minimize errors in all high current applications. Further, the LT1038 is manufactured with standard bipolar processing and has Linear Technology's high reliability.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Unless otherwise specified, these specifications apply:
 $V_{IN} - V_{OUT} = 5\text{V}$ and $I_{OUT} = 5\text{A}$. These specifications are applicable for power dissipations up to 75W. At input-output voltage differentials greater than 10V, achievable output current and power dissipation decrease due to protection circuitry.

Note 2: See thermal regulation specifications for changes in output voltage due to heating effects. Load and line regulation are measured at a constant junction temperature by low duty cycle pulse testing.

APPLICATIONS INFORMATION

General

The LT1038 develops a 1.25V reference voltage between the output and the adjustment terminal (see Figure 1). By placing a resistor, R1, between these two terminals, a constant current is caused to flow through R1 and down through R2 to set the overall output voltage. Normally this current is the specified minimum load current of 10 or 20mA. Because I_{ADJ} is very small and constant when compared with the current through R1, it represents a small error and can usually be ignored.

Bypass Capacitors

Input bypassing using a 1 μ F tantalum or 25 μ F electrolytic is recommended when the input filter capacitors are more than 5 inches from the device. Improved ripple rejection (80dB) can be accomplished by adding a 10 μ F capacitor from the adjust pin to ground. Increasing the size of the capacitor to 20 μ F will help ripple rejection at low output voltage since the reactance of this capacitor should be small compared to the voltage setting resistor, R2. For improved AC transient response and to prevent the possibil-

ity of oscillation due to unknown reactive load, a 1 μ F capacitor is also recommended at the output. Because of their low impedance at high frequencies, the best type of capacitor to use is solid tantalum.

Protection Diodes

The LT1038 does not require a protection diode from the adjustment terminal to the output (see Figure 2). Improved internal circuitry eliminates the need for this diode when the adjustment pin is bypassed with a capacitor to improve ripple rejection.

If a very large output capacitor is used, such as a 100 μ F shown in Figure 2, the regulator could be damaged or destroyed if the input is accidentally shorted to ground or crowbarred, due to the output capacitor discharging into the output terminal of the regulator. To prevent this, a diode, D1 as shown, is recommended to safely discharge the capacitor.

Figure 1. Basic Adjustable Regulator

Figure 2

APPLICATIONS INFORMATION

Load Regulation

Because the LT1038 is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the wire connecting the regulator to the load. The data sheet specification for load regulation is measured at the bottom of the package. Negative side sensing can be a true Kelvin connection if the bottom of resistor R2 is returned to the negative side of the load. Although it may not be immediately obvious, best load regulation is obtained when the top of the resistor divider, R1, is connected *directly* to the case, *not to the load*. This is illustrated in Figure 3. If

R1 were connected to the load, the effective resistance between the regulator and the load would be

$$R_p \times \left(\frac{R_2 + R_1}{R_1} \right), \quad R_p = \text{Parasitic Line Resistance.}$$

Connected as shown, R_p is not multiplied by the divider ratio. R_p is about 0.004Ω per foot using 16 gauge wire. This translates to 4mV/ft at 1A load current, so it is important to keep the lead between the regulator and the load as short as possible, and use large wire or PC board traces.

Positive Adjustable Regulator

FEATURES

- *Guaranteed* 1% Output Voltage Tolerance
- *Guaranteed* max. 0.01%/V Line Regulation
- *Guaranteed* max. 0.3% Load Regulation
- Min. 1.5A Output Current
- 100% Burn-in in Thermal Overload

APPLICATIONS

- Wide Range Power Supplies
- Constant Current Supplies
- Voltage Programmable Supplies

DESCRIPTION

The LT117A Series are 3-terminal positive adjustable voltage regulators which offer improved performance over earlier devices. A major feature of the LT117A is the output voltage tolerance is guaranteed at a maximum of $\pm 1\%$, allowing an overall power supply tolerance to be better than 3% using inexpensive 1% resistors. Line and load regulation performance has been improved as well. Additionally, the LT117A reference voltage is guaranteed not to exceed 2% when operating over the full load, line and power dissipation conditions. The LT117A adjustable regulators offer an improved solution for all positive voltage regulator requirements with load currents up to 1.5 amps.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Unless otherwise specified, these specifications apply for $V_{IN} - V_{OUT} = 5V$; and $I_{OUT} = 0.1A$ for the T0-39 and $I_{OUT} = 0.5A$ for the T0-3 and T0-220 packages. Although power dissipation is internally limited, these specifications are applicable for power dissipations of 2W for the T0-39, and 20W for the T0-3 and T0-220. P_{MAX} is 1.5A for the T0-3 and T0-220 packages and 0.5A for the T0-39.

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation. Load regulation is measured on the output pin at a point $1/8"$ below the base of the K and H package and at the junction of the wide and narrow portion of the lead on the T package.

APPLICATIONS INFORMATION

General: The LT117A develops a 1.25V reference voltage between the output and the adjustable terminal (see Figure 1). By placing a resistor, R₁, between these two terminals, a constant current is caused to flow through R₁ and down through R₂ to set the overall output voltage. Normally this current is the specified minimum load current of 5mA or 10mA.

Figure 1

Because I_{ADJ} is very small and constant when compared with the current through R₁, it represents a small error and can usually be ignored.

It is easily seen from the above equation, that even if the resistors were of exact value, the accuracy of the output is limited by the accuracy of V_{REF} . Earlier adjustable regulators had a reference tolerance of $\pm 4\%$. This tolerance is dangerously close to the $\pm 5\%$ supply tolerance required in many logic and analog systems. Further, many 1% resistors can drift 0.01%/°C adding another 1% to the output voltage tolerance.

For example, using 2% resistors and $\pm 4\%$ tolerance for V_{REF} , calculations will show that the expected range of a 5V regulator design would be $4.66V \leq V_{OUT} \leq 5.36V$ or approximately $\pm 7\%$. If the same example were used for a 15V regulator, the expected tolerance would be $\pm 8\%$. With these results most applications require some method of trimming, usually a trim pot. This solution is both expensive and not conducive to volume production.

One of the enhancements of Linear Technology's adjustable regulators over existing devices is tightened initial tolerance. This allows relatively inexpensive 1% or 2% film resistors to be used for R₁ and R₂ while setting output voltage within an acceptable tolerance range.

With a guaranteed 1% reference, a 5V power supply design, using $\pm 2\%$ resistors, would have a worst case manufacturing tolerance of $\pm 4\%$. If 1% resistors were used, the tolerance would drop to $\pm 2.5\%$. A plot of the worst case output voltage tolerance as a function of resistor tolerance is shown on the front page.

For convenience, a table of standard 1% resistor values is shown below.

Table of 1/2% and 1% Standard Resistance Values

1.00	1.47	2.15	3.16	4.64	6.81
1.02	1.50	2.21	3.24	4.75	6.98
1.05	1.54	2.26	3.32	4.87	7.15
1.07	1.58	2.32	3.40	4.99	7.32
1.10	1.62	2.37	3.48	5.11	7.50
1.13	1.65	2.43	3.57	5.23	7.68
1.15	1.69	2.49	3.65	5.36	7.87
1.18	1.74	2.55	3.74	5.49	8.06
1.21	1.78	2.61	3.83	5.62	8.25
1.24	1.82	2.67	3.92	5.76	8.45
1.27	1.87	2.74	4.02	5.90	8.66
1.30	1.91	2.80	4.12	6.04	8.87
1.33	1.96	2.87	4.22	6.19	9.09
1.37	2.00	2.94	4.32	6.34	9.31
1.40	2.05	3.01	4.42	6.49	9.53
1.43	2.10	3.09	4.53	6.65	9.76

Standard Resistance Values are obtained from the Decade Table by multiplying by multiples of 10. As an example, 1.21 can represent 1.21Ω, 12.1Ω, 121Ω, 1.21KΩ etc.

Bypass Capacitors: Input bypassing using a 1μF tantalum or 25μF electrolytic is recommended when the input filter capacitors are more than 5 inches from the device. Improved ripple rejection (80 dB) can be accomplished by adding a 10μF capacitor from the adjust pin to ground. Increasing the size of the capacitor to 20μF will help ripple rejection at low output voltage since the reactance of this capacitor should be small compared to the voltage setting resistor, R2. For improved AC transient response and to prevent the possibility of oscillation due to unknown reactive load, a 1μF capacitor is also recommended at the output. Because of their low impedance at high frequencies, the best type of capacitor to use is solid tantalum.

Protection Diodes: The LT117A/317A do not require a protection diode from the adjustment terminal to the output (see Figure 2). Improved internal circuitry

Figure 2

eliminates the need for this diode when the adjustment pin is bypassed with a capacitor to improve ripple rejection.

If a very large output capacitor is used, such as a 100μF shown in Figure 2, the regulator could be damaged or destroyed if the input is accidentally shorted to ground or crowbarred. This is due to the output capacitor discharging into the output terminal of the regulator. To prevent damage a diode D1 is recommended to safely discharge the capacitor.

Load Regulation: Because the LT117A is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the wire connecting the regulator to the load. For the data sheet specification, regulation is measured at the bottom of the package. Negative side sensing is a true Kelvin connection, with the bottom of the output divider returned to the negative side of the load. Although it may not be immediately obvious, best load regulation is obtained when the top of the divider is connected *directly* to the case *not* to the load. This is illustrated in Figure 3. If R1 were connected to the load, the effective resistance between the regulator and the load would be

$$R_p \times \left(\frac{R_2 + R_1}{R_1} \right), R_p = \text{Parasitic Line Resistance.}$$

Connected as shown, R_p is not multiplied by the divider ratio. R_p is about 0.004Ω per foot using 16 gauge wire. This translates to 4mV/ft at 1A load current, so it is important to keep the positive lead between regulator and load as short as possible.

The ● denotes the specifications which apply over the full operating temperature range.

The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

Note 1: Unless otherwise specified, these specifications apply for $V_{IN} - V_{OUT} = 5V$; and $I_{OUT} = 0.1A$ for the TO-39 and $I_{OUT} = 0.5A$ for the TO-3 package. Although power dissipation is internally limited, these specifications are applicable for power dissipations of 2W for the TO-39, and 20W for the TO-3. I_{MAX} is 1.5A for the TO-3 package and 0.5A for the TO-39.

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation.

FEATURES

- *Guaranteed* 1% Initial Tolerance of Output Voltage
- 3 Amp Output Current
- 30 Watt
- Full Internal Overload Protection
- 100% Burn-in in Thermal Limit

APPLICATIONS

- Local 5V Regulators
- On Card Regulation
- Lab Supplies
- Instrumentation Supplies

DESCRIPTION

The LT123A/LT323A is an improved version of the popular LM123/LM323 5 Volt, 3 Amp Regulator. These new devices offer maximum initial output voltage tolerance of 1% and maintain a maximum tolerance of 3% over worst case operating conditions. Line and load regulation are also improved by a factor of 2. These tightened specifications ease design and application problems since safety margins are improved. Also, error budgets in other parts of the system can be expanded, and output voltages at the end of long supply runs can be more accurately maintained.

The LT123A/LT323A incorporates Linear Technology's advanced design, process and test techniques for improved quality and reliability over similar device types. Specifically, all devices are burned in by shorting the output, thereby forcing the regulator into its current limit and eventually, thermal limit. This ensures that all device protection features are functional. A graph of the worst case output voltage, taking into account temperature, load and line variations, and power dissipation is shown below. For higher output current requirements, see the LT1003, 5V, 5A regulator data sheet.

APPLICATIONS INFORMATION

Bypass Capacitors: The LT123A does not require an output capacitor for resistive loads. For almost all applications, however, a $1\mu\text{F}$ or larger solid tantalum capacitor should be used at the output within 2" of the regulator to improve the output impedance at high frequencies. For applications where very low high frequency impedance is required, a $10\mu\text{F}$ solid tantalum output capacitor is recommended. Total output capacitance either local or distributed may be increased without limit.

A $2\mu\text{F}$ or larger solid tantalum capacitor or a $25\mu\text{F}$ aluminum capacitor, must be used at the input if the regulator is more than 4" away from the large rectifier capacitor.

Avoiding Ground Loops: For best regulation, the ground pin of the LT123A should be tied directly to the load point as shown. This prevents excess drop in load voltage caused by load current flowing through the ground return lead. This is essentially a Kelvin connection for the low side of the regulator. A Kelvin connection cannot be made for the high output of regulator because only three pins are available on the package. Therefore, every attempt should be made to minimize the resistance between the output pin of the regulator and the load. #18 gauge hookup wire has a resistance of 0.006 ohms per foot. This translates to 0.36% change in load voltage at full load current. The LT123A is specified at 1% maximum load regulation, so one foot of wire represents a significant loss of regulation. If connectors are used, careful consideration must be given to contact resistance, especially if the connector is subjected to nasty ambients, vibration, or multiple insertions.

Raw Supply: Transformer, diode, and capacitor selection for the raw supply to the LT123A is very important because of the conflicting requirements for reliability, efficiency, and resistance to "brown-out" conditions. High secondary voltage on the transformer will cause unnecessarily high power dissipation in the regulator. Too low a secondary voltage will cause the regulator output to drop out of regulation with only a small reduction in AC mains voltage. The following formula gives a good starting point for transformer selection. This formula assumes a center tapped transformer, using two rectifier diodes.

where:

$$V_{OUT} = 5V$$

$$V_{DO} = \text{Minimum input-output differential of the regulator}$$

$$V_{RECT} = \text{Rectifier forward drop at } 3I_{OUT}$$

$$V_{RIP} = \frac{1}{2} \text{ p-p capacitor ripple voltage}$$

$$\approx \frac{(5.3 \times 10^{-3})(I_{OUT})}{2C}$$

$$V_{NOM} = \text{Rated line voltage for the transformer (RMS)}$$

$$V_{LOW} = \text{Lowest expected line voltage (RMS)}$$

$$I_{OUT} = \text{DC output current}$$

*1.1 is a nominal load regulation factor for the transformer

APPLICATIONS INFORMATION

Example: $I_{OUT} = 2.5A$, $V_{OUT} = 5V$
Assume: $V_{DO} = 2.5V$, $V_{RECT} = 1.1V$, $C = 8,000\mu F$
 $V_{NOM} = 115V$, $V_{LOW} = 0.88V$

$$V_{RIP} = \frac{(5.3 \times 10^{-3})(2.5)}{2(8 \times 10^{-3})} = 0.83V$$

$$V_{RMS} = \left(\frac{5 + 2.5 + 1.1 + 0.83}{\sqrt{2}} \right) \left(\frac{115}{0.5} \right) (1.1)$$

$$= 8.03 V_{RMS}$$

$$V_{RMS} = \left(\frac{V_{OUT} + V_{DO} + V_{RECT} + V_{RIP}}{\sqrt{2}} \right) \left(\frac{V_{NOM}}{V_{LOW}} \right) (1.1^*)$$

$$I_{RMS} = (I_{OUT}) (1.2)$$

The filter capacitor should be at *least* $2000\mu F$ per amp of load current to minimize capacitor heating and ripple voltage. The diodes should be rated at 5–6 amps even though their average current is only 1.5A at full rated load current. The reason for this is that although the *average* current is 1.5A, the RMS current is typically twice this value. In addition, the diode must withstand very high surge currents during power turn-on. This surge can be 10–20 times the DC rating of the supply, depending on capacitor size and wiring resistance and inductance.

TYPICAL APPLICATIONS

† Q2 AND D1 MUST WITHSTAND LARGE SURGE CURRENTS UNTIL THE 5A FUSE BLOWS. PEAK SURGE CURRENT IS LIMITED ONLY BY THE FUSE, WIRING, AND FILTER CAP RESISTANCE.

†† TRIP POINT IS APPROXIMATELY 7.3V.

* THE 6.4V ZENER IS INTERNAL TO THE LT123A.

** Q1 MUST BE ABLE TO WITHSTAND CONTINUOUS CURRENTS OF 5A IF ADDITIONAL SYSTEM SHUTDOWN IS NOT USED.

Negative Adjustable Regulator

FEATURES

- *Guaranteed* 1% Initial Voltage Tolerance
- *Guaranteed* 0.01%/V Line Regulation
- *Guaranteed* 0.5% Load Regulation
- *Guaranteed* 0.02%/W Thermal Regulation
- 100% Burn-in in Thermal Limit

APPLICATIONS

- Adjustable Power Supplies
- System Power Supplies
- Precision Voltage/Current Regulators
- On-Card Regulators

DESCRIPTION

The LT137A/LT337A negative adjustable regulators will deliver up to 1.5Amps output current over an output voltage range of -1.2V to -37V . Linear Technology has made significant improvements in these regulators compared to previous devices, such as better line and load regulation, and a maximum output voltage error of 1%.

Every effort has been made to make these devices easy to use and difficult to damage. Internal current and power limiting coupled with true thermal limiting prevents device damage due to overloads or shorts, even if the regulator is not fastened to a heat sink.

Maximum reliability is attained with Linear Technology's advanced processing techniques combined with a 100% burn-in in the thermal limit mode. This assures that all device protection circuits are working and eliminates field failures experienced with other regulators that receive only standard electrical testing.

The ● denotes the specifications which apply over the full operating temperature range.

The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

Note 1: Unless otherwise indicated, these specifications apply: $|V_{IN} - V_{OUT}| = 5V$; and $I_{OUT} = 0.1A$ for the H package, $I_{OUT} = 0.5A$ for the K and T packages. Power dissipation is internally limited. However, these specifications apply for power dissipation up to 2W for the H package and 20W for the K and T packages. $I_{MAX} = 1.5A$ for the K and T packages, and 0.2A for the H package.

Note 2: Testing is done using a pulsed low duty cycle technique. See thermal regulation specifications for output changes due to heating effects. Load regulation is measured on the output pin at a point 1/8" below the base of the K and H package and at the junction of the wide and narrow portion of the lead on the T package.

Note 3: Load Regulation for the LT337AT is the same as for LM337T.

Note 4: Guaranteed on LT137A and LT337A, but not 100% tested in production.

Current Limit

Adjustment Current

APPLICATION INFORMATION

Output Voltage: The output voltage is determined by two external resistors, R_1 and R_2 (see Figure 1). The exact formula for the output voltage is:

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ}(R_2)$$

Where: V_{REF} = Reference Voltage, I_{ADJ} = Adjustment Pin Current. In most applications, the second term is small enough to be ignored, typically about 0.5% of V_{OUT} . In more critical applications, the exact formula should be used, with I_{ADJ} equal to 65 μA . Solving for R_2 yields:

$$R_2 = \frac{V_{OUT} - V_{REF}}{\frac{V_{REF}}{R_1} + I_{ADJ}}$$

Smaller values of R_1 and R_2 will reduce the influence of I_{ADJ} on the output voltage, but the no-load current drain on the regulator will be increased. Typical values for R_1 are between 100 Ω and 300 Ω , giving 12.5mA and 4.2mA no-load current respectively. There is an additional consideration in selecting R_1 , the minimum load current specification of the regulator. The operating current of the LT137A flows from input to output. If this current is not absorbed by the load, the output of the regulator will rise above the regulated value. The current drawn by R_1 and R_2 is normally high enough to

absorb the current, but care must be taken in no-load situations where R_1 and R_2 have high values. The maximum value for the operating current, which must be absorbed, is 5mA for the LT137A. If input-output voltage differential is less than 10V, the operating current that must be absorbed drops to 3mA.

Figure 1

EXAMPLES:

1. A precision 10V regulator to supply up to 1Amp load current.
 - a. Select $R_1 = 100\Omega$ to minimize effect of I_{ADJ}
 - b. Calculate $R_2 = \frac{V_{OUT} - V_{REF}}{\frac{V_{REF}}{R_1} - I_{ADJ}} = \frac{10V - 1.25V}{\frac{1.25V}{100\Omega} - 65\mu A} = 704\Omega$
2. A 15V regulator to run off batteries and supply 50mA.
 - $V_{IN\ MAX} = 25V$
 - a. To minimize battery drain, select R_1 as high as possible

$$R_1 = \frac{1.25V}{3mA} = 417\Omega, \text{ use } 404\Omega, 1\%$$

b. The high value for R_1 will exaggerate the error due to I_{ADJ} , so the exact formula to calculate R_2 should be used.

$$R_2 = \frac{V_{OUT} - V_{Ref}}{\frac{V_{Ref}}{R_1} - I_{ADJ}} = \frac{15V - 1.25V}{\frac{1.25V}{404\Omega} - 65 \times 10^{-6}} = 4539\Omega$$

Use $R_2 = 4530\Omega$

Capacitors and Protection Diodes: An output capacitor, C_3 , is required to provide proper frequency compensation of the regulator feedback loop. A $1\mu F$ or larger solid tantalum capacitor is generally sufficient for this purpose if the 1MHz impedance of the capacitor is 2Ω or less. High Q capacitors, such as Mylar, are not recommended because they tend to reduce the phase margin at light load currents. Aluminum electrolytic capacitors may also be used, but the minimum value should be $10\mu F$ to ensure a low impedance at 1MHz. The output capacitor should be located within a few inches of the regulator to keep lead impedance to a minimum. The following caution should be noted: if the output voltage is greater than 6V and an output capacitor greater than $20\mu F$ has been used, it is possible to damage the regulator if the input voltage becomes shorted, due to the output capacitor discharging into the regulator. This can be prevented by using diode D1 (see Figure 2) between the input and the output.

The input capacitor, C_2 , is only required if the regulator is more than 4 inches from the raw supply filter capacitor.

Bypassing the Adjustment Pin: The adjustment pin of the LT137A may be bypassed with a capacitor to ground, C_1 , to reduce output ripple, noise, and impedance. These parameters scale directly with output voltage if the adjustment pin is not bypassed. A bypass capacitor reduces ripple, noise, and impedance to that of a 1.25V regulator. In a 15V regulator for example, these parameters are improved by $15V/1.25V = 12$ to 1. This improvement holds only for those frequencies where the impedance of the bypass capacitor is less than R_1 . Ten microfarads is generally sufficient for 60Hz power line applications where the ripple frequency is 120Hz, since $X_c = 130\Omega$. The capacitor should have a voltage rating at least as high as the output voltage of the regulator. Values larger than $10\mu F$ may be used, but if the output is larger than 25V, a diode, D2, should be added between the output and adjustment pins (see Figure 2).

* D1 protects the regulator from input shorts to ground. It is required only when C_3 is larger than $20\mu F$ and V_{OUT} is larger than 6V.

** D2 protects the adjust pin of the regulator from output shorts if C_2 is larger than $10\mu F$ and V_{OUT} is larger than $-25V$.

Figure 2

Proper Connection of Divider Resistors: The LT137A has an excellent load regulation specification of 0.5% and is measured at a point $1/8"$ from the bottom of the package. To prevent degradation of load regulation, the resistors which set output voltage, R_1 and R_2 , must be connected as shown in Figure 3. Note that the positive side of the load has a true force and sense (Kelvin) connection, but the negative side of the load does not.

Figure 3

R_1 should be connected *directly* to the output lead of the regulator, as close as possible to the specified point $1/8"$ from the case. R_2 should be connected to the positive side of the load separately from the positive (ground) connection to the raw supply. With this arrangement, load regulation is degraded only by the resistance between the regulator output pin and the load. If R_1 is connected to the load, regulation will be degraded.

TYPICAL APPLICATIONS

The output stability, load regulation, line regulation, thermal regulation, temperature drift, long term drift, and noise, can be improved by a factor of 6.6 over the standard regulator configuration. This assumes a zener whose drift and noise is considerably better than the regulator itself. The LM329B has 20PPM/°C maximum drift and about 10 times lower noise than the regulator.

In the application shown below, regulators #2 to "N" will track regulator #1 to within $\pm 24\text{mV}$ initially, and to $\pm 60\text{mV}$ over all load, line, and temperature conditions. If any regulator output is shorted to ground, all other outputs will drop to $\approx -2\text{V}$. Load regulation of regulators 2 to "N" will be improved by $V_{\text{OUT}}/1.25\text{V}$ compared to a standard regulator, so regulator #1 should be the one which has the lowest load current.

High Voltage Negative Adjustable Regulators

FEATURES

- 50V Operation
- *Guaranteed* 1% Initial Voltage Tolerance
- *Guaranteed* 0.01%/V Line Regulation
- *Guaranteed* 0.5% Load Regulation
- *Guaranteed* 0.02%/W Thermal Regulation
- 100% Burn-in in Thermal Limit

APPLICATIONS

- Adjustable Power Supplies
- System Power Supplies
- Precision Voltage/Current Regulators
- On-Card Regulators

The LT137AHV/LM137HV negative high voltage adjustable regulators will deliver up to 1.5 Amps output current over an output voltage range of -1.2V to -47V . Linear Technology has made significant improvements in these regulators compared to previous devices, such as better line and load regulation, and a maximum output voltage error of 1% for the LT137AHV and LT337AHV.

Every effort has been made to make these devices easy to use and difficult to damage. Internal current and power limiting coupled with true thermal limiting prevents device damage due to overloads or shorts, even if the regulator is not fastened to a heat sink.

Maximum reliability is attained with Linear Technology's advanced processing techniques combined with a 100% burn-in in the thermal limit mode. This assures that all device protection circuits are working and eliminates field failures experienced with other regulators that receive only standard electrical testing. For performance curves and applications circuits see the LT137A series data sheet.

5 Amp Positive Adjustable Voltage Regulator

FEATURES

- *Guaranteed* 1% Initial Tolerance
- *Guaranteed* 0.3% Load Regulation
- *Guaranteed* 5 Amp Output Current
- 100% Thermal Limit Burn-in
- 12 Amp Transient Output Current

APPLICATIONS

- High Power Linear Regulator
- Battery Chargers
- Power Driver
- Constant Current Regulator

DESCRIPTION

The LT138A series of adjustable regulators provide 5 amps output current over an output voltage range of 1.2 volts to 32 volts. The internal voltage reference is trimmed to less than 1%, enabling a very tight output voltage. In addition to excellent line and load regulation, with full overload protection, the LT138A incorporates new current limiting circuitry allowing large transient load currents to be handled for short periods. Transient load currents of up to 12 amps can be supplied without limiting, eliminating the need for a large output capacitor.

The LT138A is an improved version of the popular LM138 with improved circuit design and advanced process techniques to provide superior performance and reliability.

The graph below shows the significant improvement in output voltage tolerance achieved by using the LT138A or LT338A.

TYPICAL PERFORMANCE CHARACTERISTICS

APPLICATIONS INFORMATION

General

The LT138A develops a 1.25V reference voltage between the output and the adjustable terminal (see Figure 1). By placing a resistor, R₁, between these two terminals, a constant current is caused to flow through R₁ and down through R₂ to set the overall output voltage. Normally this current is the specified minimum load current of 5mA or 10mA. Because I_{ADJ} is very small and constant when compared with the current through R₁, it represents a small error and can usually be ignored. It is easily seen from the output voltage equation, that even if the resistors were of exact value, the accuracy of the output is limited by the accuracy of V_{REF}. Earlier adjustable regulators had a reference tolerance of ±4% which is dangerously

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2$$

Basic Adjustable Regulator
Figure 1

close to the ±5% supply tolerance required in many logic and analog systems. Further, even 1% resistors can drift 0.01%/°C, adding additional error to the output voltage tolerance.

LT138A/LT338A LM138/LM338

For example, using 2% resistors and $\pm 4\%$ tolerance for V_{REF} , calculations will show that the expected range of a 5V regulator design would be $4.66V \leq V_{OUT} \leq 5.36V$ or approximately $\pm 7\%$. If the same example were used for a 15V regulator, the expected tolerance would be $\pm 8\%$. With these results most applications required some method of trimming, usually a trim pot. This solution is both expensive and not conducive to volume production.

One of the enhancements of Linear Technology's adjustable regulators over existing devices is the tightened initial tolerance of V_{REF} . This allows relatively inexpensive 1% or 2% film resistors to be used for R1 and R2 to set the output voltage within an acceptable tolerance.

With a guaranteed 1% reference, a 5V power supply design, using $\pm 2\%$ resistors, would have a worst case manufacturing tolerance of $\pm 4\%$. If 1% resistors are used, the tolerance will drop to $\pm 2.5\%$. A plot of the worst case output voltage tolerance as a function of resistor tolerance is shown on the front page.

For convenience, a table of standard 1% resistor values is shown below.

Table of 1/2% and 1% Standard Resistance Values

1.00	1.47	2.15	3.16	4.64	6.81
1.02	1.50	2.21	3.24	4.75	6.98
1.05	1.54	2.26	3.32	4.87	7.15
1.07	1.58	2.32	3.40	4.99	7.32
1.10	1.62	2.37	3.48	5.11	7.50
1.13	1.65	2.43	3.57	5.23	7.68
1.15	1.69	2.49	3.65	5.36	7.87
1.18	1.74	2.55	3.74	5.49	8.06
1.21	1.78	2.61	3.83	5.62	8.25
1.24	1.82	2.67	3.92	5.76	8.45
1.27	1.87	2.74	4.02	5.90	8.66
1.30	1.91	2.80	4.12	6.04	8.87
1.33	1.96	2.87	4.22	6.19	9.09
1.37	2.00	2.94	4.32	6.34	9.31
1.40	2.05	3.01	4.42	6.49	9.53
1.43	2.10	3.09	4.53	6.65	9.76

Standard Resistance Values are obtained from the Decade Table by multiplying by multiples of 10. As an example, 1.21 can represent 1.21 Ω , 12.1 Ω , 121 Ω , 1.21K Ω etc.

Bypass Capacitors

Input bypassing using a 1 μ F tantalum or 25 μ F electrolytic is recommended when the input filter capacitors are more than 5 inches from the device. Improved ripple rejection (80 dB) can be accomplished by adding a

10 μ F capacitor from the adjust pin to ground. Increasing the size of the capacitor to 20 μ F will help ripple rejection at low output voltage since the reactance of this capacitor should be small compared to the voltage setting resistor, R2. For improved AC transient response and to prevent the possibility of oscillation due to unknown reactive load, a 1 μ F capacitor is also recommended at the output. Because of their low impedance at high frequencies, the best type of capacitor to use is solid tantalum.

Protection Diodes

The LT138A/338A do not require a protection diode from the adjustment terminal to the output (see figure 2). Improved internal circuitry eliminates the need for this diode when the adjustment pin is bypassed with a capacitor to improve ripple rejection.

Figure 2

If a very large output capacitor is used, such as a 100 μ F shown in figure 2, the regulator could be damaged or destroyed if the input is accidentally shorted to ground or crowbarred, due to the output capacitor discharging into the output terminal of the regulator. To prevent this, a diode D1 as shown, is recommended to safely discharge the capacitor.

Load Regulation

Because the LT138A is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the wire connecting the regulator to the load. The data sheet specification for load regulation is measured at the bottom of the package. Negative side sensing is a true Kelvin connection, with the bottom of the output divider returned to the negative side of the load. Although it may not be immediately obvious, best load regulation is obtained when the top of the resistor divider, (R1), is connected *directly* to the case *not to the load*. This is illustrated in Figure 3. If R1 were connected to the

load, the effective resistance between the regulator and the load would be

$$R_p \times \left(\frac{R_2 + R_1}{R_1} \right), R_p = \text{Parasitic Line Resistance.}$$

Connected as shown, R_p is not multiplied by the divider ratio. R_p is about 0.004Ω per foot using 16 gauge wire. This translates to 4mV/ft at 1A load current, so it is important to keep the positive lead between regulator and load as short as possible, and use large wire or PC board traces.

Connections For Best Load Regulation

DESCRIPTION

The LT150A Series are 3-terminal positive adjustable voltage regulators which offer improved performance over earlier devices. A major feature of the LT150A/350A is the output voltage tolerance is guaranteed at a maximum of $\pm 1\%$, allowing an overall power supply tolerance to be better than 3% using inexpensive 1% resistors. Line and load regulation performance has been improved as well. Additionally, the LT150A/350A reference voltage is guaranteed not to exceed 2% when operating over the full load, line and power dissipation conditions. The LT150A/350A adjustable regulators offer an improved solution for all positive voltage regulator requirements with load currents up to 3 amps.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Unless otherwise specified, these specifications apply for $V_{IN} - V_{OUT} = 5V$ and $I_{OUT} = 1.5A$. These specifications are applicable for power dissipations up to 30W for the K package and up to 25W for the T package. Power dissipation is guaranteed at these values up to 15 Volts input-output differential. Above 15 Volts input-output differential power dissipation is limited by device internal protection circuitry.

Note 2: Regulation is measured at a constant T_J . Changes in output due to heating must be taken into account separately. Pulse testing with low duty cycle is used.

APPLICATION INFORMATION

General

The LT150A develops a 1.25V reference voltage between the output and the adjustable terminal (see Figure 1). By placing a resistor, R_1 , between these two terminals, a constant current is caused to flow through R_1 and down through R_2 to set the overall output voltage. Normally this current is the specified minimum load current of 5mA or 10mA.

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2$$

Basic Adjustable Regulator
Figure 1

Because I_{ADJ} is very small and constant when compared with the current through R_1 , it represents a small error and can usually be ignored. It is easily seen from the above equation, that even if the resistors were of exact value, the accuracy of the output is limited by the accuracy of V_{REF} . Earlier adjustable regulators had a reference tolerance of $\pm 4\%$ which is

dangerously close to the $\pm 5\%$ supply tolerance required in many logic and analog systems. Further, even 1% resistors can drift $0.01\%/^\circ C$, adding additional error to the output voltage tolerance.

For example, using 2% resistors and $\pm 4\%$ tolerance for V_{REF} , calculations will show that the expected range of a 5V regulator design would be $4.66V \leq V_{OUT} \leq 5.36V$ or approximately $\pm 7\%$. If the same example were used for a 15V regulator, the expected tolerance would be $\pm 8\%$. With these results most applications required some method of trimming, usually a trim pot. This solution is both expensive and not conducive to volume production.

One of the enhancements of Linear Technology's adjustable regulators over existing devices is the tightened initial tolerance of V_{REF} . This allows relatively inexpensive 1% or 2% film resistors to be used for R_1 and R_2 to set the output voltage within an acceptable tolerance.

With a guaranteed 1% reference, a 5V power supply design, using $\pm 2\%$ resistors, would have a worst case manufacturing tolerance of $\pm 4\%$. If 1% resistors were used, the tolerance would drop to $\pm 2.5\%$. A plot of the worst case output voltage tolerance as a function of resistor tolerance is shown on the front page.

For convenience, a table of standard 1% resistor values is shown below.

1.43	2.10	3.09	4.53	6.65	9.76

Standard Resistance Values are obtained from the Decade Table by multiplying by multiples of 10. As an example, 1.21 can represent 1.21Ω, 12.1Ω, 121Ω, 1.21KΩ etc.

Bypass Capacitors

Input bypassing using a 1μF tantalum or 25μF electrolytic is recommended when the input filter capacitors are more than 5 inches from the device. Improved ripple rejection (80 dB) can be accomplished by adding a 10μF capacitor from the adjust pin to ground. Increasing the size of the capacitor to 20μF will help ripple rejection at low output voltage since the reactance of this capacitor should be small compared to the voltage setting resistor, R2. For improved AC transient response and to prevent the possibility of oscillation due to unknown reactive load, a 1μF capacitor is also recommended at the output. Because of their low impedance at high frequencies, the best type of capacitor to use is solid tantalum.

Protection Diodes

The LT150A/350A do not require a protection diode from the adjustment terminal to the output (see Figure 2). Improved internal circuitry eliminates the need for this diode when the adjustment pin is bypassed with a capacitor to improve ripple rejection.

Figure 2

If a very large output capacitor is used, such as a 100μF shown in Figure 2, the regulator could be damaged or destroyed if the input is accidentally shorted to ground or crowbarred, due to the output capacitor discharging into the output terminal of the regulator. To prevent this, a diode D1 as shown, is recommended to safely discharge the capacitor.

Load Regulation

Because the LT150A is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the wire connecting the regulator to the load. The data sheet specification for load regulation is measured at the bottom of the package. Negative side sensing is a true Kelvin connection, with the bottom of the output divider returned to the negative side of the load. Although it may not be immediately obvious, best load regulation is obtained when the top of the resistor divider (R1) is connected *directly* to the case *not to the load*. This is illustrated in Figure 3. If R1 were connected to the load, the effective resistance between the regulator and the load would be

$$R_p \times \left(\frac{R_2 + R_1}{R_1} \right), R_p = \text{Parasitic Line Resistance.}$$

Connected as shown, R_p is not multiplied by the divider ratio. R_p is about 0.004Ω per foot using 16 gauge wire. This translates to 4mV/ft at 1A load current, so

is important to keep the positive lead between regulator and load as short as possible, and use large wire or PC board traces.

Connections for Best Load Regulation

AD580

- FEATURES -

- 2.5V Output
- Direct Replacement for Analog Devices
- Selected Parts with 10ppm/°C TC
- Low Quiescent Current

- MINI DESCRIPTION -

Alternate source for industry standard 2.5V 3 terminal reference

AD581

- FEATURES -

- 10V Output
- Direct Replacement for Analog Devices
- Selected Parts with 10ppm/°C TC
- Low Quiescent Current

- MINI DESCRIPTION -

Alternate source for industry standard 10V 3-terminal reference.

LM129/329

- FEATURES -

- Low Noise
- Low Cost
- Max Temperature Drift Selections 10, 20, 50 and 100 ppm/°C
- Wide Operating Current Range

- MINI DESCRIPTION -

Subsurface zener reference with wide operating current range from 600μA to 15mA. Similar to LM199/399 without stabilizing heater on the die.

LM199A/199 LM399A/399

- FEATURES -

- Ultra Low Drift
- Very Low Noise
- Wide Operating Current Range
- Provided with Thermal Shield
- Excellent Long Term Stability
- Low Hysteresis
- Guaranteed Long Term Stability Available

- MINI DESCRIPTION -

An on board stabilizing heater keeps the die at constant temperature. Reference is a low noise subsurface zener. Excellent long term stability.

LT1004 LM185/385

- FEATURES -

- Micropower
- 1.235V and 2.5V Available
- Low Dynamic Impedance
- Wide Operating Current Range
- Very Tight Tolerance

- MINI DESCRIPTION -

Bandgap reference with operating current range as low as 10μA. Low noise and good long term stability.

VOLTAGE REFERENCE SELECTION GUIDE

LT1009 LM136/336

- FEATURES -

- No Adjustment Needed on LT1009
- Temperature Coefficient or Voltage Easily Adjusted on LM136
- Wide Operating Current Range
- Low Cost
- 2.5V
- Very Tight Tolerance

- MINI DESCRIPTION -

General purpose reference using bandgap circuit. Low cost, medium performance.

LT1019

*DO NOT CONNECT EXTERNAL CIRCUITRY TO THESE PINS

- FEATURES -

- 2.5V, 5V and 10V Versions
- Plug-In Replacement for Many Devices
- Series or Shunt Operation
- Low Drift—3ppm/°C Typ.
- 0.05% Initial Tolerance
- 100% Noise Tested
- Optional Chip Heater Can Be Used for Lower Drift
- Temperature Output

- MINI DESCRIPTION -

Curvature corrected bandgap design for very low drift and tight initial tolerance. Replaces and upgrades REF-01, REF-02, MC14XX and other popular series type references.

LT1021

*DO NOT CONNECT EXTERNAL CIRCUITRY TO THESE PINS

** NO TRIM PIN ON LT1021-7. DO NOT CONNECT EXTERNAL CIRCUITRY TO PIN 5 ON LT1021-7.

- FEATURES -

- Ultra Low Drift
- Trimmed Output Voltage
- Very Low Noise
- Operates in Series or Shunt Mode
- Replaces REF01, REF02, LM368, MC1400 and MC1404 with Improved Stability, Noise and Drift

- MINI DESCRIPTION -

Trimmed voltage reference with ultra low drift. Reference is a low noise subsurface zener. Available in 5V, 7V and 10V versions. The 7V and 10V versions can be used as 2-terminal shunt regulators as well as series references.

VOLTAGE REFERENCE SELECTION GUIDE

LT1029

- FEATURES -

- 0.2% Output Tolerance
- 0.5Ω Shunt Impedance
- 600μA to 10mA Operating Current
- Pin Compatible with LM136-5
- 20ppm/°C Max. Drift
- Output Voltage Trim does not Affect Drift
- Can be Used as Positive or Negative Reference

- MINI DESCRIPTION -

Precision 3 terminal shunt 5V bandgap reference. Very low drift and tight initial output tolerance.

LT1031/LH0070

- FEATURES -

- 10V Output
- Ultra Low Drift
- Very Low Noise
- Trimmed Output Voltage
- Operates in Series or Shunt Mode
- Pin Compatible with AD581
- LH0070 is a Direct Replacement for NSC LH0070

- MINI DESCRIPTION -

Very low tempco is achieved without chip heater. The LT1031 can replace the AD581 with better specifications.

LT1034

- FEATURES -

- *Guaranteed* Drift (1.2V) of 20ppm/°C and 40ppm/°C
- 1.2V and 7V Reference
- 1.2V Reference operates 20μA to 20mA
- 1% Tolerance on 1.2V Reference
- 7V Reference Operates 100μA to 20mA
- Compatible with the LM385 and LT1004

- MINI DESCRIPTION -

The LT1034 is a bandgap 1.2V reference with low operating current and low temperature coefficient, combined with a 7V sub-surface zener reference on the same chip.

REF-01/REF-02

- FEATURES -

- Direct Replacement for PMI Devices
- Low Drift
- High Line Rejection
- Low Supply Current
- Temperature Output on REF-02

- MINI DESCRIPTION -

Industry standard 5V and 10V bandgap voltage references.

*DO NOT CONNECT EXTERNAL CIRCUITRY TO THESE PINS
**REF-02 ONLY

FEATURES

- Guaranteed $\pm 4\text{mV}$ initial accuracy LT1004-1.2
- Guaranteed $\pm 20\text{mV}$ accuracy LT1004-2.5
- Guaranteed $10\mu\text{A}$ operating current
- Guaranteed temperature performance
- Operates up to 20mA
- Very low dynamic impedance

APPLICATIONS

- Portable meter references
- Portable test instruments
- Battery operated systems
- Current loop instrumentation

DESCRIPTION

The LT1004 Micropower Voltage References are two terminal bandgap reference diodes designed to provide high accuracy and excellent temperature characteristics at very low operating currents. Optimization of the key parameters in the design, processing and testing of the device results in accuracy specifications previously attainable only with selected units. Below is a distribution plot of reference voltage for a typical lot of LT1004-1.2. Virtually all of the units fall well within the prescribed limits of $\pm 4\text{mV}$.

The LT1004 is a pin for pin replacement for the LM185/385 series of references with improved accuracy specifications. More important, the LT1004 is an attractive device for use in systems where accuracy was previously obtained at the expense of power consumption and trimming.

For a low drift micropower reference with guaranteed temperature coefficient, see the LT1034 data sheet.

FEATURES

- 0.2% Initial Tolerance Max
- *Guaranteed* Temperature Stability
- Maximum 0.6 Ω Dynamic Impedance
- Wide Operating Current Range
- Directly Interchangeable with LM136 for Improved Performance
- No Adjustments Needed for Minimum Temperature Coefficient

APPLICATIONS

- Reference for 5V Systems
- 8 Bit A/D and D/A Reference
- Digital Voltmeters
- Current Loop Measurement and Control Systems
- Power Supply Monitor

DESCRIPTION

The LT1009 is a precision trimmed 2.500 Volt shunt regulator diode featuring a maximum initial tolerance of only ± 5 mV. The low dynamic impedance and wide operating current range enhances its versatility. The 0.2% reference tolerance is achieved by on-chip trimming which not only minimizes the initial voltage tolerance but also minimizes the temperature drift.

Even though no adjustments are needed with the LT1009, a third terminal allows the reference voltage to be adjusted $\pm 5\%$ to calibrate out system errors. In many applications, the LT1009 can be used as a pin-to-pin replacement of the LM136H-2.5 and the external trim network eliminated.

For a lower drift 2.5V reference, see the LT1019 data sheet.

- Temperature Output

APPLICATIONS

- A to D and D to A Converters
- Precision Regulators
- Constant Current Sources
- V to F Converters
- Bridge Excitation

DESCRIPTION

The LT1019 is a third generation bandgap voltage reference utilizing thin film technology and a greatly improved curvature correction technique. Wafer level trimming of both reference and output voltage combines to produce units with high yields to very low TC and tight initial tolerance of output voltage.

The LT1019 can both sink and source up to 10mA and can be used in either the series or shunt mode. This allows the reference to be used for both positive and negative output voltages without external components. Minimum input-output voltage is less than 1V in the series mode, providing improved tolerance of low line conditions.

The LT1019 is available in three voltages: 2.5V, 5V, and 10V. It is a direct replacement for most bandgap references presently available including AD580, AD581, REF-01, REF-02, MC1400, MC1404 and LM168.

For ultra low drift applications ($< 2\text{ppm}/^{\circ}\text{C}$), the LT1019 can be operated in a heated mode by driving an internal resistor with an external amplifier. Chip temperature can be externally set for minimum power consumption.

For a 6.2V version of the LT1019, consult the factory.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: These are high power conditions and are therefore guaranteed only at temperatures equal to or below 35°C.

Note 2: Output voltage drift is measured using the box method. Output voltage is recorded at T_{MIN} , 25°C, and T_{MAX} . The lowest of these three readings is subtracted from the highest and the resultant difference is divided by $(T_{MAX} - T_{MIN})$.

Note 3: Line regulation and load regulation are measured on a pulse basis with low duty cycle. Effects due to die heating must be taken into account separately. See thermal regulation and application section.

Note 4: Load regulation is measured at a point $\frac{1}{8}$ " below the base of the package with Kelvin contacts.

Note 5: I_{MIN} is equal to minimum shunt current when in the shunt mode (V_{IN} disconnected). In sink mode, $I_{MIN} = 0$.

Note 6: Thermal regulation is caused by die temperature gradients created by load current or input voltage changes. This effect must be added to normal line or load regulation.

Note 7: Minimum shunt current is measured with shunt voltage held 20mV below value measured at 1mA shunt current.

Note 8: Minimum input-output voltage is measured by holding input voltage 0.5V above the nominal output voltage, while measuring $V_{IN} - V_{OUT}$.

Note 9: RMS noise is measured with a single high pass filter at 10Hz and a 2-pole low pass filter at 1kHz. The resulting output is full wave rectified and then integrated for a fixed period, making the final reading an average as opposed to RMS. A correction factor of 1.1 is used to convert from average to RMS, and a second correction of 0.88 is used to correct for the non-ideal bandpass of the filters.

Peak-to-peak noise is measured with a single high pass filter at 0.1Hz and a 2-pole low pass filter at 10Hz. The unit is enclosed in a still-air environment to eliminate thermocouple effects on the leads. Test time is 10 seconds.

Line Regulation

APPLICATIONS INFORMATION

Line and Load Regulation

Line regulation on the LT1019 is nearly perfect. A 10V change in input voltage causes a typical output shift of less than 5ppm. Load regulation (sourcing current) is nearly as good. A 5mA change in load current shifts output voltage by only 100 μ V. These are *electrical* effects, measured with low duty cycle pulses to eliminate heating effects. In real world applications, the *thermal* effects of load and line changes must be considered.

Two separate thermal effects are evident in monolithic circuits. One is a gradient effect, where power dissipation on the die creates temperature gradients. These gradients can cause output voltage shifts *even if the overall temperature coefficient of the reference is zero*. The LT1019, unlike previous references, specifies thermal regulation caused by die temperature gradients. The specification is 0.5ppm/mW. To calculate the effect on

APPLICATIONS INFORMATION

output voltage, simply multiply the *change* in device power dissipation by the thermal regulation specification. Example: a 10V device with a nominal input voltage of 15V and load current of 5mA. Find the effect of an input voltage change of 1V and a load current change of 2mA.

$$\Delta P (\text{line change}) = (\Delta V_{IN})(I_{LOAD}) = (1V)(5mA) = 5mW$$

$$\Delta V_{OUT} = (0.5\text{ppm/mW})(5mW) = 2.5\text{ppm}$$

$$\Delta P (\text{load change}) = (\Delta I_{LOAD})(V_{IN} - V_{OUT}) \\ = (2mA)(5V) = 10mW$$

$$\Delta V_{OUT} = (0.5\text{ppm/mW})(10mW) = 5\text{ppm}$$

Even though these effects are small, they should be taken into account in critical applications, especially where input voltage or load current is high.

The second thermal effect is overall die temperature change. The magnitude of this change is the product of change in power dissipation times the thermal resistance (Θ_{JA}) of the IC package $\approx (100^{\circ}\text{C/W} - 150^{\circ}\text{C/W})$. The effect on reference output is calculated by multiplying die temperature change by the temperature drift specification of the reference. Example: same conditions as above with $\Theta_{JA} = 150^{\circ}\text{C/W}$ and an LT1019 with 20ppm/ $^{\circ}\text{C}$ drift specification.

$$\Delta P (\text{line change}) = 5mW$$

$$\Delta V_{OUT} = (5mW)(150^{\circ}\text{C/W})(20\text{ppm}/^{\circ}\text{C}) \\ = 15\text{ppm}$$

$$\Delta P (\text{load change}) = 10mW$$

$$\Delta V_{OUT} = (10mW)(150^{\circ}\text{C/W})(20\text{ppm}/^{\circ}\text{C}) \\ = 30\text{ppm}$$

These calculations show that thermally induced output voltage variations can easily exceed the electrical effects. In critical applications where shifts in power dissipation are expected, a small clip-on heat sink can significantly improve these effects by reducing overall die temperature change. Alternately, an LT1019A can be used with 4 times lower TC. If warm-up drift is of concern, these measures will also help. With warm-up drift, *total* device

power dissipation must be considered. In the example given, warm-up drift (worst-case) is equal to:

$$\text{Warm-up drift} = [(V_{IN})(I_Q) + (V_{IN} - V_{OUT})(I_{LOAD})] \\ [(\Theta_{JA})(TC)]$$

$$\text{with } I_Q (\text{quiescent current}) = 0.6mA,$$

$$\text{warm-up drift} = [(15V)(0.6mA) + (5V)(5mA)] \\ [(150^{\circ}\text{C/W})(25\text{ppm}/^{\circ}\text{C})] \\ = 127.5\text{ppm}$$

Note that 74% of the warm-up drift is due to load current times input-output differential. This emphasizes the importance of keeping both these numbers low in critical applications. With heavy loads, warm-up drift can also be improved using the technique described under "Driving Loads Above 10mA", or by heat sinking.

Driving Loads Above 10mA

The LT1019 is guaranteed to drive loads up to 10mA. Much higher load currents can be accommodated by adding an external PNP (see application circuits), but this is often not necessary for relatively constant loads in the 10mA–40mA range. Instead, a resistor is added from input to output with a value chosen to supply most of the load current. The LT1019 can both sink and source current, so it maintains proper reference voltage as long as the difference between resistor current and load current does not exceed 10mA. The example shown in Figure 1 assumes an input voltage of 14.5V to 15.5V, a reference voltage of 10V, and a load current of 25mA–35mA. The resistor is chosen to supply nominal load current at nominal input voltage. This causes the LT1019 to operate in the source or sink mode, depending on load or line conditions. The resistor value may be modified in some cases to create all-source or all-sink conditions to minimize power dissipation in the reference or to keep power supply current to a minimum.

Figure 1

APPLICATIONS INFORMATION

Note that line regulation is now affected by reference output impedance. R1 should have a wattage rating high enough to withstand full input voltage if output shorts must be tolerated. Even with load currents below 10mA, R1 can be used to reduce power dissipation in the LT1019 for lower warm-up drift, etc.

Output Trimming

Output voltage trimming on the LT1019 is nominally accomplished with a potentiometer connected from output to ground with the wiper tied to the trim pin. The LT1019 was made compatible with existing references, so the trim range is large; +6%, -6% for the LT1019-2.5, +5%, -13% for the LT1019-5, and +5%, -27% for the LT1019-10. This large trim range makes precision trimming rather difficult. One solution is to insert resistors in series with both ends of the potentiometer. This has the disadvantage of potentially poor tracking between the fixed resistors and the potentiometer. A second method of reducing trim range is to insert a resistor in series with the wiper of the potentiometer. This works well only for very small trim range because of the mismatch in TCs between the series resistor and the internal thin film resistors. These film resistors can have a TC as high as 500ppm/°C. That same TC is then transferred to the change in output voltage; a 1% shift in output voltage causes a (500ppm) (1%) = 5ppm/°C change in output voltage drift. The worst-case error in initial output voltage

for the LT1019 is 0.2%, so a series resistor is satisfactory if the output is simply trimmed to nominal value. 1ppm/°C TC shift would be the maximum expected.

Using the Temp Pin

The LT1019 has a TEMP pin like several other bandgap references. The voltage on this pin is directly proportional to absolute temperature (PTAT) with a slope of $\approx 2.1\text{mV}/^\circ\text{C}$. Room temperature voltage is therefore $\approx (295^\circ\text{K}) (2.1\text{mV}/^\circ\text{C}) = 620\text{mV}$. Previous bandgap references have been very sensitive to any loading on the TEMP pin because it is an integral part of the reference "core" itself. The LT1019 "taps" the core at a special point which has much less effect on the reference. The relationship between TEMP pin loading and a change in reference output voltage is less than $0.05\%/ \mu\text{A}$, about 10 times improvement over previous references.

The TEMP pin can be used to sense chip temperature in applications where the chip is forced to constant temperature (see "Heated Mode") or to sense ambient temperature in applications where the temperature difference between chip and ambient is tolerable or can be calibrated out. Typical chip temperature rise over ambient is $\approx 2^\circ\text{C}$ with no output load and 15V input voltage, but it could be as high as 6°C with a 5mA load and 5V input-output differential. A Centigrade thermometer is shown in the application circuits. This particular configuration has

Wide Range Trim $\geq \pm 5\%$

Trimming LT1019-5 Output to 5.120V

Narrow Trim Range ($\pm 0.2\%$)

Trimming LT1019-10 Output to 10.240V

APPLICATIONS INFORMATION

the advantage of trimming "zero" and "slope" simultaneously. The PTAT nature of the TEMP pin output has a known predictable relationship between initial zero error and slope. This circuit takes advantage of that relationship by trimming at a point that corrects the zero and slope errors simultaneously.

A simple over-temp circuit is also shown in the application section using an LT1011 comparator. This circuit is intended to be an *ambient* sensor, so temperature rise in the reference must be considered when setting trip level. R2B is adjusted by connecting a DVM across the inputs of the comparator and setting the DVM to read 2.1mV for each degree above room temperature. A 70°C trip would require $(2.1\text{mV})(70^\circ\text{C} - 22^\circ\text{C}) = 101\text{mV}$. R3 provides about 1°C hysteresis to prevent oscillations.

Heated Mode

The LT1019 has an internal heater resistor which can be used to maintain constant chip temperature. The TEMP

output is used to sense chip temperature and, in conjunction with an external amplifier, forms a complete thermal control loop. Using the circuit shown in Figure 2, chip temperature is maintained extremely accurately. Residual reference output voltage shift with ambient temperature changes is less than 2ppm/°C. This small residue is the result of chip temperature gradients and heater current flowing in the ground pin of the reference. Heater power required to maintain a chip temperature of 70°C is about 300mW at 25°C ambient. With a heater resistance of 400Ω nominal, this requires a heater voltage of 11V and heater current of 28mA. Lower ambient temperatures will require proportionately higher power levels.

The amplifier used in this application is non-critical. For single supply operation, it must have a common-mode range down to 0.6V. With a negative supply available, this restriction is removed. Higher supply voltages (>15V) may require a small heat sink on Q1.

Heated Mode Reduces Temperature Drift to Less than 2ppm/°C

FEATURES

- Pin Compatible with Most Bandgap Reference Applications, Including Ref 01, Ref 02, LM368, MC1400, and MC1404, with Greatly Improved Stability, Noise, and Drift
- Ultra Low Drift—5ppm/°C Max Slope
- Trimmed Output Voltage
- Operates in Series or Shunt Mode
- Output Sinks and Sources in Series Mode
- Very Low Noise < 1ppm p-p (0.1Hz to 10Hz)
- > 100dB Ripple Rejection
- Minimum Input-Output Differential of 1V
- 2ppm/°C Max Drift Available on Request
- 100% Noise Tested

APPLICATIONS

- A to D and D to A Converters
- Precision Regulators
- Digital Voltmeters
- Inertial Navigation Systems
- Precision Scales
- Portable Reference Standard

DESCRIPTION

The LT1021 is a precision reference with ultra low drift and noise, extremely good long term stability, and almost total immunity to input voltage variations. The reference output will both source and sink up to 10mA. Three voltages are available; 5V, 7V and 10V. The 7V and 10V units can be used as shunt regulators (two terminal zeners) with the same precision characteristics as the three terminal connection. Special care has been taken to minimize thermal regulation effects and temperature induced hysteresis.

The LT1021 references are based on a buried zener diode structure which eliminates noise and stability problems associated with surface breakdown devices. Further, a subsurface zener exhibits better temperature drift and time stability than even the best band-gap references.

Unique circuit design makes the LT1021 the first IC reference to offer ultra low drift without the use of high power on-chip heaters.

The LT1021-7 uses no resistive divider to set output voltage, and therefore exhibits the best long term stability and temperature hysteresis. The LT1021-5 and LT1021-10 are intended for systems requiring a precise 5V or 10V reference, with an initial tolerance as low as $\pm 0.05\%$.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Output voltage is measured immediately after turn-on. Changes due to chip warm-up are typically less than 0.005%.

Note 2: Temperature coefficient is measured by dividing the change in output voltage over the temperature range by the change in temperature. Separate tests are done for hot and cold; T_{MIN} to 25°C, and 25°C to T_{MAX} . Incremental slope is also measured at 25°C.

Note 3: Line and load regulation are measured on a pulse basis. Output changes due to die temperature change must be taken into account separately. Package thermal resistance is 150°C/W for TO-5 (H), and 130°C/W for N.

Note 4: Shunt mode regulation is measured with the input open. With the input connected, shunt mode current can be reduced to 0mA. Load regulation will remain the same.

Note 5: RMS noise is measured with a single high pass filter at 10Hz and a 2-pole low pass filter at 1kHz. The resulting output is full wave rectified and then integrated for a fixed period, making the final reading an average as opposed to RMS. A correction factor of 1.1 is used to convert from average to RMS, and a second correction of 0.88 is used to correct for the non-ideal bandpass of the filters.

Peak-to-peak noise is measured with a single high pass filter at 0.1Hz and a 2-pole low pass filter at 10Hz. The unit is enclosed in a still-air environment to eliminate thermocouple effects on the leads. Test time is 10 seconds.

Note 6: Consult factory for units with long term stability data.

APPLICATIONS INFORMATION

Effect of Reference Drift on System Accuracy

A large portion of the temperature drift error budget in many systems is the system reference voltage. This graph indicates the maximum temperature coefficient allowable if the reference is to contribute no more than $\frac{1}{2}$ LSB error to the overall system performance. The example shown is a 12-bit system designed to operate over a temperature range from 25°C to 65°C. Assuming the system calibration is performed at 25°C, the temperature span is 40°C. It can be seen from the graph that the temperature coefficient of the reference must be no worse than 3ppm/°C if it is to contribute less than $\frac{1}{2}$ LSB error. For this reason, the LT1021 family has been optimized for low drift.

Trimming Output Voltage

LT1021-10

The LT1021-10 has a trim pin for adjusting output voltage. The impedance of the trim pin is about 12kΩ with a nominal open circuit voltage of 5V. It is designed to be driven from a source impedance of 3kΩ or less to minimize changes in the LT1021 TC with output trimming. Attenuation between the trim pin and the output is 70:1. This allows ± 70 mV trim range when the trim pin is tied to the wiper of a potentiometer connected between the output and ground. A 10kΩ potentiometer is recommended, preferably a 20 turn cermet type with stable characteristics over time and temperature.

The LT1021-10 "C" version is pre-trimmed to ± 5 mV and therefore can utilize a restricted trim range. A 75kΩ resistor in series with a 20kΩ potentiometer will give ± 10 mV trim range. Effect on output TC will be only 1ppm/°C for the ± 5 mV trim needed to set the "C" device to 10.000V.

LT1021-5

The LT1021-5 does have an output voltage trim pin, but the TC of the nominal 4V open circuit voltage at this pin is about -1.7 mV/°C. For the voltage trimming not to affect reference output TC, the external trim voltage must track the voltage on the trim pin. Input impedance of the trim pin is about 100kΩ and attenuation to the output is 13:1. The technique shown below is suggested for trimming the output of the LT1021-5 while maintaining minimum shift in output temperature coefficient. The R1/R2 ratio is chosen to minimize interaction of trimming and TC shifts, so the exact values shown should be used.

LT1021-7

The 7V version of the LT1021 has no trim pin because the internal architecture does not have a point which could be driven conveniently from the output. Trimming must therefore be done externally, as is the case with ordinary reference diodes. Unlike these diodes, however, the output of the LT1021 can be loaded with a trim potentiometer. The following trim techniques are suggested; one for voltage output, and one for current output. The voltage output is trimmed for 6.95V. Current output is 1mA, as shown, into a summing junction, but all resistors may be scaled for currents up to 10mA.

APPLICATIONS INFORMATION

Both of these circuits use the trimmers in a true potentiometric mode to reduce the effects of trimmer TC. The voltage output has a 200Ω impedance, so loading must be minimized. In the current output circuit, R_1 determines output current. It should have a TC commensurate with the LT1021 or track closely with the feedback resistor around the op amp.

internal current drain on the output, actual worst-case occurs at $I_{LOAD} = 0$ on LT1021-5, $I_{LOAD} = -0.8\text{mA}$ (sinking) on LT1021-7, and $I_{LOAD} = 1.4\text{mA}$ (sinking) on LT1021-10. Significantly better load transient response is obtained by moving slightly away from these points. See Load Transient Response curves for details. In general, best transient response is obtained when the output is sourcing current. In critical applications, a $10\mu\text{F}$ solid tantalum capacitor with several ohms in series provides optimum output bypass.

Kelvin Connections

Although the LT1021 does not have true force/sense capability at its outputs, significant improvements in ground loop and line loss problems can be achieved with proper hook-up. In series mode operation, the ground pin of the LT1021 carries only $\approx 1\text{mA}$ and can be used as a sense line, greatly reducing ground loop and loss problems on the low side of the reference. The high side supplies load current so line resistance must be kept low. Twelve feet of #22 gauge hook up wire or 1 foot of 0.025 inch printed circuit trace will create 2mV loss at 10mA output current. This is equivalent to 1LSB in a 10V , 12-bit system.

The circuits below show proper hook up to minimize errors due to ground loops and line losses. Losses in the output lead can be greatly reduced by adding a PNP boost transistor if load currents are 5mA or higher. R_2 can be added to further reduce current in the output sense lead.

*RESISTOR TC DETERMINES I_{OUT} TC

**TC $\leq 10 \times R_1$ TC. R_2 AND R_3 SCALE WITH R_1 FOR DIFFERENT OUTPUT CURRENTS.

Capacitive Loading and Transient Response

The LT1021 is stable with all capacitive loads, but for optimum settling with load transients, output capacitance should be under 1000pF . The output stage of the reference is class AB with a fairly low idling current. This makes transient response worst-case at light load currents. Because of

 $R2 = 2.4k$ (LT1021-5), $3k$ (LT1021-7), $5.6k$ (LT1021-10)

Effects of Air Movement on Low Frequency Noise

The LT1021 has very low noise because of the buried zener used in its design. In the 0.1Hz to 10Hz band, peak-to-peak noise is about 0.5ppm of the DC output. To achieve this low noise, however, care must be taken to shield the reference from ambient air turbulence. Air movement can create noise because of thermoelectric differences between IC package leads (especially kovar lead TO-5) and printed circuit board materials and/or sockets. Power dissipation in the reference, even though it rarely exceeds 20mW, is enough to cause small temperature gradients in the package leads. Variations in thermal resistance, caused by uneven air flow, create differential lead temperatures, thereby causing thermoelectric voltage noise at the output of the reference. The XY plotter trace shown below dramatically illustrates this effect. The first half of the plot was done with the LT1021

shielded from ambient air with a small foam cup. The cup was then removed for the second half of the trace. Ambient in both cases was a lab environment with no excessive air turbulence from air conditioners, opening/closing doors, etc. Removing the foam cup increases the output noise by almost an order of magnitude in the 0.01Hz to 1Hz band! The kovar leads of the TO-5 (H) package are the primary culprit. Alloy 42 and copper lead frames used on dual-in-line packages are not nearly as sensitive to thermally generated noise because they are intrinsically matched.

There is nothing magical about foam cups—any enclosure which blocks air flow from the reference will do. Smaller enclosures are better since they do not allow the build-up of internally generated air movement. Naturally, heat generating components external to the reference itself should not be included inside the enclosure.

Negative Shunt Reference Driven by Current Source

The circuit diagram shows a precision current source. A -15V supply is connected to a 1.2k resistor, which is in series with the GND pin of an LT1021-10 trimmer. The other end of the trimmer is connected to the REF pin of a CMOS DAC (7520, etc.). The DAC's fB pin is connected to ground through a 30pF capacitor. The DAC's I_{OUT} pin is connected to the inverting input of an LT1007C op-amp. The op-amp's non-inverting input is connected to ground. The op-amp's output is connected to a 10V F.S. (Full Scale) output point. This output point is also connected to a 100Ω resistor (R4) and a 4.02k resistor (R3) to ground. A 1% tolerance is indicated for the 4.02k resistor. The text '*TO LESS THAN 200ppm/°C' is at the bottom.

- 0.5Ω Shunt Impedance
- 600μA to 10mA Operating Current
- Pin Compatible with LM136-5
- 20ppm/°C Max. Drift
- Output Voltage Trim does not Affect Drift
- Can be Used as Positive or Negative Reference

APPLICATIONS

- A-to-D and D-to-A Converters
- Precision Regulators
- Precision Current Sources
- V to F and F to V Converters

DESCRIPTION

The LT1029 is a 5V bandgap reference intended for use in the shunt or "zener" mode, allowing it to be used as either a positive or negative reference. The output is pretrimmed to $\pm 0.2\%$ accuracy with 20ppm/°C maximum temperature drift. A trim pin allows additional output adjustment for even more precise output voltage.

Operating current range for the LT1029 is 600μA to 10mA. Extremely low dynamic impedance allows excellent output regulation even with fluctuating operating current.

The LT1029 will replace an LM136-5 or LM336-5 and simplify circuits using the "minimum temperature coefficient" trim network. The LT1029 does not require this special network to meet its temperature drift specification and these application network components are simply removed. If output trimming is required for initial accuracy, the diodes in the trim network should be replaced with jumpers.

APPLICATIONS INFORMATION

Output Trimming

Output voltage trimming on the LT1029 is nominally accomplished with a potentiometer connected from output to ground with the wiper tied to the trim pin. The LT1029 was made compatible with existing references, so the trim range is large; $+5\%$, -13% . This large trim range makes precision trimming rather difficult. One solution is to insert resistors in series with both ends of the potentiometer. This has the disadvantage of potentially poor tracking between the fixed resistors and the potentiometer. A second method of reducing trim range is to insert a resistor in series with the wiper of the potentiometer. This works well only for a very

small trim range because of the mismatch in TCs between the series resistor and the internal thin film resistors. These film resistors can have a TC as high as $500\text{ppm}/^\circ\text{C}$. That same TC is then transferred to the change in output voltage; a 1% shift in output voltage causes a $(500\text{ppm})(1\%) = 5\text{ppm}/^\circ\text{C}$ change in output voltage drift. The worst-case error in initial output voltage for the LT1029A is 0.2% and for the LT1029 is 1% , so a series resistor is satisfactory if the output is simply trimmed to nominal value. $1\text{ppm}/^\circ\text{C}$ TC shift would be the maximum expected for the LT1029A and $5\text{ppm}/^\circ\text{C}$ for the LT1029.

Wide Trim Range ($+5\%$, -13%)

Narrow Trim Range

TRIM RANGE
 0.4% — LT1029A, $R1 = 750\text{k}$
 1.2% — LT1029, $R1 = 250\text{k}$

APPLICATIONS INFORMATION

Shunt Capacitance

The LT1029 is stable with all values of shunt capacitance, but values between 300pF and 0.01 μ F are not recommended because they cause longer settling following a

transient in operating current. A 1 μ F solid tantalum capacitor is suggested for most situations where bypassing is desirable.

- Inertial Navigation Systems
- Precision Scales
- Portable Reference Standard

*See LH0070 Electrical Characteristics table and AD581 cross reference guide.

DESCRIPTION

The LT1031 is a precision 10V reference with ultra low drift and noise, extremely good long term stability, and almost total immunity to input voltage variations. The reference output will both source and sink up to 10mA and can be used as a shunt regulator (two terminal zener) with the same precision characteristics as the three terminal connection. Special care has been taken to minimize thermal regulation effects and temperature induced hysteresis.

The LT1031 reference is based on a buried zener diode structure which eliminates noise and stability problems associated with surface breakdown devices. Further, a subsurface zener exhibits better temperature drift and time stability than even the best band-gap references.

Unique circuit design makes the LT1031 the first three terminal IC reference to offer ultra low drift without the use of high power on-chip heaters. Output voltage is pretrimmed to 0.05% accuracy.

The LT1031 can be used as a plug-in replacement for the AD581 and LH0070*, with improved electrical and thermal performance.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Output voltage is measured immediately after turn-on. Changes due to chip warm-up are typically less than 0.005%.

Note 2: Temperature coefficient is measured by dividing the change in output voltage over the temperature range by the change in temperature. Separate tests are done for hot and cold; T_{MIN} to $25^\circ C$, and $25^\circ C$ to T_{MAX} . **Incremental slope is also measured at $25^\circ C$.** For LT1031BMH, the 5ppm/ $^\circ C$ drift specification is for $-25^\circ C$ to $85^\circ C$. Drift over the full $-55^\circ C$ to $+125^\circ C$ range is guaranteed to 7ppm/ $^\circ C$.

Note 3: Line and load regulation are measured on a pulse basis. Output changes due to die temperature change must be taken into account separately. Package thermal resistance is $150^\circ C/W$.

Note 4: Shunt mode regulation is measured with the input open. With the input connected, shunt mode current can be reduced to 0mA. Load regulation will remain the same.

Note 5: Temperature drift is guaranteed from $-25^\circ C$ to $+85^\circ C$ on LH0070.

Note 6: See curve for guaranteed minimum V_{IN} versus I_{OUT} .

Note 7: Guaranteed by design.

CROSS REFERENCE

The following cross reference guide may be used to select LT1031 grades which meet or exceed output voltage, temperature drift, load and line regulation, and output current specifications of the AD581 reference. Parameters such as noise, hysteresis, and long term stability will be significantly better for all LT1031 grades compared to the AD581.

APPLICATIONS INFORMATION

Trimming Output Voltage

The LT1031 output can be trimmed by driving the ground pin. The suggested method is shown in the accompanying figure. A 5Ω resistor is inserted in series with the ground pin and the top of the resistor is supplied current from a trim potentiometer. This technique requires fairly high trim current—up to 1.5mA from the LT1031 or 3.5mA from the -15V supply, but it is necessary to maintain low drift in the reference. Ground pin current changes in the LT1031 (with temperature) could be as high as $4\mu\text{A}/^\circ\text{C}$. This, coupled with the 5Ω external resistor, creates up to $2\text{ppm}/^\circ\text{C}$ drift in the reference ($5\Omega \times 4\mu\text{A}/^\circ\text{C} = 20\mu\text{V}/^\circ\text{C} = 2\text{ppm}/^\circ\text{C}$). If induced drift higher than this can be tolerated, all resistor values in the trim circuit can be raised proportionately to reduce current drain.

Output Voltage Trimming

*CAN BE INCREASED TO $5.6\text{k}\Omega$ FOR LT1031B AND LH0070-2

**INCREASE TO 100Ω FOR LT1031D

Effect of Reference Drift on System Accuracy

A large portion of the temperature drift error budget in many systems is the system reference voltage. This graph indicates the maximum temperature coefficient allowable if the reference is to contribute no more than $1/2\text{LSB}$ error to the overall system performance. The example shown is a 12-bit system designed to operate over a temperature range from 25°C to 65°C . Assuming the system calibration is performed at 25°C , the temperature span is 40°C . It can be seen from the graph that the temperature coefficient of the reference must be no worse than $3\text{ppm}/^\circ\text{C}$ if it is to contribute less than $1/2\text{LSB}$ error. For this reason, the LT1031 has been optimized for low drift.

Maximum Allowable Reference Drift

Capacitive Loading and Transient Response

The LT1031 is stable with all capacitive loads, but for optimum settling with load transients, output capacitance should be under 1000pF . The output stage of the reference is class AB with a fairly low idling current. This makes transient response worst-case at light load currents. Because of internal current drain on the output, actual worst-case occurs at $I_{\text{LOAD}} = 1.4\text{mA}$ (sinking). Significantly better load transient response is obtained by moving slightly away from these points. See Load Transient Response curves for details. In general, best transient response is obtained when the output is sourcing current. In critical applications, a $10\mu\text{F}$ solid tantalum capacitor with several ohms in series provides optimum output bypass.

Kelvin Connections

Although the LT1031 does not have true force/sense capability at its outputs, significant improvements in ground loop and line loss problems can be achieved with proper hook-up. In series mode operation, the ground pin of the LT1031 carries only $\approx 1\text{mA}$ and can be used as a sense line, greatly reducing ground loop and loss problems on the low side of the reference. The high side supplies load current so line resistance must be kept low. Twelve feet of #22 gauge hook up wire or 1 foot of 0.025 inch printed circuit trace will create 2mV loss at 10mA output current. This is equivalent to 1LSB in a 10V , 12-bit system.

APPLICATIONS INFORMATION

The circuits below show proper hook up to minimize errors due to ground loops and line losses. Losses in the output lead can be greatly reduced by adding a PNP boost transistor if load currents are 5mA or higher. R2 can be added to further reduce current in the output sense lead.

Standard Series Mode

Series Mode with Boost Transistor

*OPTIONAL—REDUCES CURRENT IN OUTPUT SENSE LEAD

Effects of Air Movement on Low Frequency Noise

The LT1031 has very low noise because of the buried zener used in its design. In the 0.1Hz to 10Hz band, peak-to-peak noise is about 0.5ppm of the DC output. To achieve this low noise, however, care must be taken to shield the reference from ambient air turbulence. Air

movement can create noise because of thermoelectric differences between IC package leads (especially kovar lead TO-5) and printed circuit board materials and/or sockets. Power dissipation in the reference, even though it rarely exceeds 20mW, is enough to cause small temperature gradients in the package leads. Variations in thermal resistance, caused by uneven air flow, create differential lead temperatures, thereby causing thermoelectric voltage noise at the output of the reference. The XY plotter trace shown below dramatically illustrates this effect. The first half of the plot was done with the LT1031 shielded from ambient air with a small foam cup. The cup was then removed for the second half of the trace. Ambient in both cases was a lab environment with no excessive air turbulence from air conditioners, opening/closing doors, etc. Removing the foam cup increases the output noise by almost an order of magnitude in the 0.01Hz to 1Hz band! The kovar leads of the TO-5 (H) package are the primary culprit. Alloy 42 and copper lead frames used on dual-in-line packages are not nearly as sensitive to thermally generated noise because they are intrinsically matched.

There is nothing magical about foam cups—any enclosure which blocks air flow from the reference will do. Smaller enclosures are better since they do not allow the build-up of internally generated air movement. Naturally, heat generating components external to the reference itself should not be included inside the enclosure.

- 1.2V 1% Initial Tolerance
- 20 μ A to 20mA Operation
- 1 Ω Dynamic Impedance
- 7V, 100 μ A Reference

APPLICATIONS

- Portable Meters
- Precision Regulators
- Calibrators

DESCRIPTION

The LT1034 is a micropower, precision 1.2V reference combined with a 7V auxiliary reference. The 1.2V reference is a trimmed, thin-film, band-gap voltage reference with 1% initial tolerance and guaranteed 20ppm/°C temperature drift. Operating on only 20 μ A, the LT1034 offers guaranteed drift, low temperature cycling hysteresis and good long term stability. The low dynamic impedance makes the LT1034 easy to use from unregulated supplies. The 7V reference is a subsurface zener device for less demanding applications.

The LT1034 1.2V reference can be used as a high performance upgrade of the LM385 or LT1004.

- Precision Regulators
- Constant Current Sources
- V to F Converters
- Bridge Excitation

DESCRIPTION

The AD580/AD581 are bandgap voltage references utilizing thin film technology and a greatly improved curvature correction technique. Wafer level trimming of both reference and output voltage combines to produce units with high yields to very low TC and tight initial tolerance of output voltage.

The AD580/AD581 can both sink and source up to 10mA and can be used in either the series or shunt mode. This allows the reference to be used for both positive and negative output voltages without external components. Minimum input-output voltage is less than 1V in the series mode, providing improved tolerance of low line conditions.

For voltage references with improved specifications, please see the LT1019, LT1021, and LT1031 data sheets.

DESCRIPTION

The LM129 temperature compensated 6.9 Volt zener references provide excellent stability over time and temperature, very low dynamic impedance and a wide operating current range. The device achieves low dynamic impedance by incorporating a high gain shunt regulator around the zener. The excellent noise performance of the device is achieved by using a "buried zener" design which eliminates surface noise phenomenon associated with ordinary zeners. To serve a wide variety of applications, the LM129 is available in several temperature coefficient grades and two package styles. A 20mA positive current source application is shown below.

Constant Current Source and Temperature Sensor

FEATURES

- $1\mu\text{A}$ to 10mA Operation
- $0.02\%/V$ Regulation
- 0.8V to 40V Operating Voltage
- Can be Used as Linear Temperature Sensor
- Draws No Reverse Current
- Supplied in Standard Transistor Packages

APPLICATIONS

- Current Mode Temperature Sensing
- Constant Current Source for Shunt References
- Cold Junction Compensation
- Constant-Gain Bias for Bipolar Differential Stage
- Micropower Bias Networks
- Buffer for Photoconductive Cell
- Current Limiter

DESCRIPTION

The LM134 is a three-terminal current source designed to operate at current levels from $1\mu\text{A}$ to 10mA , as set by an external resistor. The device operates as a true two-terminal current source, requiring no extra power connections or input signals. Regulation is typically $0.02\%/V$ and terminal-to-terminal voltage can range from 800mV to 40V .

Because the operating current is *directly proportional to absolute temperature* in degrees Kelvin, the device will also find wide applications as a temperature sensor. The temperature dependence of the operating current is $+0.336\%/^{\circ}\text{C}$ at room temperature. For example, a device operating at $298\mu\text{A}$ will have a temperature coefficient of $+1\mu\text{A}/^{\circ}\text{C}$. The temperature dependence is extremely accurate and repeatable. Devices specified as temperature sensors in the $100\mu\text{A}$ to 1mA range are the LM134-3, LM234-3 and the LM134-6, LM234-6, with the dash numbers indicating $\pm 3^{\circ}\text{C}$ and $\pm 6^{\circ}\text{C}$ accuracies, respectively.

If a zero temperature coefficient current source is required, this is easily achieved by adding a diode and a resistor.

Note 1: Unless otherwise specified, tests are performed at $T_J = 25^\circ C$ with pulse testing so that junction temperature does not change during test.

Note 2: Set current is the current flowing into the V^+ pin. It is determined by the following formula: $I_{SET} = 67.7mV/R_{SET}$ ($@25^\circ C$). Set current error is expressed as a percent deviation from this amount. I_{SET} increases at $0.336\%/^\circ C @ T_J = 25^\circ C$.

Note 3: I_{SET} is directly proportional to absolute temperature ($^\circ K$). I_{SET} at any temperature can be calculated from: $I_{SET} = I_0 (T/T_0)$ where I_0 is I_{SET} measured at T_0 ($^\circ K$).

Note 4: $V_{MAX} = 40V$ for LM134 and $30V$ for other grades.

Operating Current vs Temperature

APPLICATIONS INFORMATION

Basic Theory of Operation

The equivalent circuit of the LM134 is shown in Figure 1. A reference voltage of 64mV is applied to the minus input of A1 with respect to the V^- pin. A1 serves the drive to Q2 to keep the R pin at 64mV, independent of the value of R_{SET} . Transistor Q1 is matched to Q2 at a 17:1 ratio so that the current flowing out of the V^- pin is always 1/18 of the total current into the V^+ pin. This total current is called I_{SET} and is equal to

$$\left(\frac{64\text{mV}}{R_{SET}}\right) \left(\frac{18}{17}\right) = \frac{67.7\text{mV}}{R_{SET}}$$

Figure 1

The 67.7mV equivalent reference voltage is directly proportional to absolute temperature in degrees Kelvin (see curve, "Operating Current vs Temperature"). This means that the reference voltage can be plotted as a straight line going from 0mV at absolute zero temperature to 67.7mV at 298°K (25°C). The slope of this line is $67.7\text{mV}/298 = 227\mu\text{V}/^\circ\text{C}$.

The accuracy of the device is specified as a percent error at room temperature, or in the case of the -3 and -6 devices, as both a percent error and an equivalent temperature error. The LM134 operating current changes at a percent rate equal to $(100)(227\mu\text{V}/^\circ\text{C})/(67.7\text{mV}) = 0.336\%/^\circ\text{C}$ at 25°C, so each 1% operating current error is equivalent to $\approx 3^\circ\text{C}$ temperature error when the device is used as a temperature sensor. The slope accuracy (temperature coefficient) of the LM134 is expressed as a

ratio compared to unity. The LM134-3, for instance, is specified at 0.98T to 1.02T, indicating that the maximum slope error of the device is $\pm 2\%$ when the room temperature current is set to the exact desired value.

Supply Voltage Slew Rate

At slew rates above a given threshold (see curve), the LM134 may exhibit non-linear current shifts. The slewing rate at which this occurs is directly proportional to I_{SET} . At $I_{SET} = 10\mu\text{A}$, maximum dv/dt is $0.01\text{V}/\mu\text{s}$; at $I_{SET} = 1\text{mA}$, the limit is $1\text{V}/\mu\text{s}$. Slew rates above the limit do not harm the LM134, or cause large currents to flow.

Thermal Effects

Internal heating can have a significant effect on current regulation for I_{SET} greater than $100\mu\text{A}$. For example, each 1V increase across the LM134 at $I_{SET} = 1\text{mA}$ will increase junction temperature by $\approx 0.4^\circ\text{C}$ in still air. Output current (I_{SET}) has a temperature coefficient of $\approx 0.33\%/^\circ\text{C}$, so the change in current due to temperature rise will be $(0.4)(0.33) = 0.132\%$. This is a 10:1 degradation in regulation compared to true electrical effects. Thermal effects, therefore, must be taken into account when DC regulation is critical and I_{SET} exceeds $100\mu\text{A}$. Heat sinking of the TO-46 package or the TO-92 leads can reduce this effect by more than 3:1.

Shunt Capacitance

In certain applications, the 15pF shunt capacitance of the LM134 may have to be reduced, either because of loading problems or because it limits the AC output impedance of the current source. This can be easily accomplished by buffering the LM134 with an FET, as shown in the applications. This can reduce capacitance to less than 3pF and improve regulation by at least an order of magnitude. DC characteristics (with the exception of minimum input voltage) are not affected.

APPLICATIONS INFORMATION

Noise

Current noise generated by the LM134 is approximately 4 times the shot noise of a transistor. If the LM134 is used as an active load for a transistor amplifier, input referred noise will be increased by about 12dB. In many cases, this is acceptable and a single stage amplifier can be built with a voltage gain exceeding 2000.

Lead Resistance

The sense voltage which determines the operating current of the LM134 is less than 100mV. At this level, thermocouple or lead resistance effects should be minimized by locating the current setting resistor physically close to the device. Sockets should be avoided if possible. It takes only 0.7Ω contact resistance to reduce output current by 1% at the 1mA level.

Start-Up Time

The LM134 is designed to operate at currents as low as $1\mu\text{A}$. This requires that internal biasing current be well below that level because the device achieves its wide operating current range by using part of the operating current as bias current for the internal circuitry. To ensure start-up, however, a fixed trickle current must be provided internally. This is typically in the range of 20nA–200nA and is provided by the special ultra-low I_{SS} FETs shown in the Schematic Diagram as Q7 and Q8. The start-up time of the LM134 is determined by the I_{SS} of these FETs and the capacitor C1. This capacitor must charge to approximately 500mV before Q3 turns on to start normal circuit operation. This takes as long as (500mV) (50pF)/(20nA) = 1.25ms for very low I_{SS} values.

Using the LM134 as a Temperature Sensor

Because it has a highly linear output characteristic, the LM134 makes a good temperature sensor. It is particularly useful in remote sensing applications because it is a current output device and is therefore not affected by long wire runs. It is easy to calibrate, has good long term stability, and can be interfaced directly with most data acquisition systems, eliminating the expensive preamplifiers required for thermocouples and platinum sensors.

A typical temperature sensor application is shown in Figure 2. The LM134 operating current at 25°C is set at $298\mu\text{A}$ by the 226Ω resistor, giving an output of $1\mu\text{A}/^\circ\text{C}$. The current flows through the twisted pair sensor leads to the $10\text{k}\Omega$ termination resistor, which converts the current output to a voltage of $10\text{mV}/^\circ\text{C}$ referred to ground. The voltage across the $10\text{k}\Omega$ resistor will be 2.98V at 25°C , with a slope of $10\text{mV}/^\circ\text{C}$. The simplest way to convert this signal to a Centigrade scale is to subtract a constant 2.73V in software. Alternately, a hardware conversion can be used, as shown in Figure 3, using an LT1009 as a level shifter to offset the output to a Centigrade scale.

The resistor (R_{SET}) used to set the operating current of the LM134 in temperature sensing applications should have low temperature coefficient and good long term stability.

Figure 2. Kelvin Temperature Sensor

Figure 3. Centigrade Temperature Sensor

APPLICATIONS INFORMATION

30ppm/°C drift in the resistor will change the slope of the temperature sensor by 1%, assuming that the resistor is at the same temperature as the sensor, which is usually the case since the resistor should be located physically close to the LM134 to prevent errors due to wire resistance. A long term shift of 0.3% in the resistor will create a 1°C temperature error. The long term drift of the LM134 is typically much better than this, so stable resistors must be used for best long term performance.

Calibration of the LM134 as a temperature sensor is extremely easy. Referring to Figure 2, calibration is achieved by trimming the termination resistor. *This theoretically trims both zero and slope simultaneously for Centigrade and Fahrenheit applications.* The initial errors in the LM134 are directly proportional to absolute temperature, just like the actual output. This allows the sensor to be trimmed at any temperature and have the slope error be corrected at the same time. Residual slope error is typically less than 1% after this single trim is completed.

The two trims shown in Figure 3 are still intended to be a "one point" temperature calibration, where the zero and the slope are trimmed at a single temperature. The LT1009 reference is adjusted to give 2.700V at node "a" at $T_{\text{SENSOR}} = 25^{\circ}\text{C}$. The 1k trimmer then adjusts the output for 0.25V, completing the calibration. If the calibration is to be done at a temperature other than 25°C, trim the LT1009 for $2.7025 - (1\mu\text{A})[T_{\text{SENSOR}} (^{\circ}\text{C})](100\Omega)$ at node "a", then adjust the 1k trimmer for proper output.

If higher accuracy is required, a two point calibration technique can be used. In Figure 4, separate zero and slope trims are provided. Residual non-linearity is now the limitation on accuracy. Non-linearity of the LM134 in a 100°C span is typically less than 0.5°C. This particular method of trimming has the advantage that the slope trim does not interact with the zero trim. Trim procedure is to adjust for zero output with $T_{\text{SENSOR}} = 0^{\circ}\text{C}$, then trim slope for proper output at some convenient second temperature. No further trimming is required.

DESCRIPTION

The LM136-2.5 is a general purpose shunt regulator diode designed to operate over a wide current range while maintaining good stability with time and temperature. The third terminal allows either the temperature coefficient to be minimized or the reference voltage to be adjusted without changing the temperature coefficient. Because it operates as a shunt regulator it can be used equally well as a positive or negative reference.

The LM136-2.5 is available with initial tolerances as low as 1% in either a TO-46 metal can for hermetic requirements or a low cost TO-92 plastic package.

Linear's advanced design, test and process techniques have optimized the LM136-2.5 to achieve superior performance and reliability over previous designs. For more demanding precision reference applications requiring very low initial tolerance and temperature coefficients, consult the LT1009 data sheet. A typical 2.5 Volt reference with trim is shown below.

DESCRIPTION

The LM185-1.2 is a two terminal band gap reference diode that has been designed for applications which require precision performance with micropower operation. The device provides guaranteed operating specifications at currents as low as 10 μ A. The nominal voltage is 1.235V with both 1% and 2% tolerances available. Some additional features are: maximum dynamic impedance of 1 Ω , low noise and excellent stability over time and temperature. Advanced design, processing and testing techniques make Linear's LM185-1.2 a superior choice over previous designs. A micro-power 5V reference application is shown below. For guaranteed TC, micropower references, see the LT1034 data sheet.

FEATURES

- 20 μ A to 20mA operating range
- *Guaranteed* 1% initial voltage tolerance
- *Guaranteed* 1 Ω dynamic impedance
- Very low power consumption

APPLICATIONS

- Portable meter references
- Portable test instruments
- Battery operated systems
- Panel meters
- Current loop instrumentation

DESCRIPTION

The LM185-2.5 is a two terminal band gap reference diode that has been designed for applications which require precision performance with micropower operation. The device provides guaranteed operating specifications at currents as low as 20 μ A. The nominal voltage is 2.5V with both 1% and 2% tolerances available. Some additional features are: maximum dynamic impedance of 1 Ω , low noise and excellent stability over time and temperature. The advanced design, processing and testing techniques make Linear's LM185-2.5 a superior choice over previous designs. A circuit for cold junction compensation of a thermocouple is shown below.

- Laboratory measurement equipment
- Industrial monitor/control instruments
- High accuracy data converters

DESCRIPTION

The LM199/399 precision reference features excellent temperature stability over a wide range of voltage, temperature, and operating current conditions. A stabilizing heater is incorporated with the active zener on a monolithic substrate which nearly eliminates changes in voltage with temperature. The subsurface zener operates over a current range of 0.5mA to 10mA, and offers minimal noise and excellent long term stability.

Ideal applications for the LM199/399 include digital voltmeters, precision calibration equipment, current sources and a variety of other precision low cost references. A 10 volt buffered reference application is shown below.

The ● denotes the specifications which apply over full operating temperature range.

Note 1: The substrate is electrically connected to the negative terminal of the temperature stabilizer. The voltage that can be applied to either terminal of the reference is 40V more positive or 0.1V more negative than the substrate.

Note 2: These specifications apply for 30V applied to the temperature stabilizer and $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$ for the LM199; and $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$ for the LM399.

Note 3: Devices with maximum guaranteed long term stability of 20 ppm/ $\sqrt{\text{kHz}}$ are available. Drift decreases with time.

Note 4: This initial current can be reduced by adding an appropriate resistor and capacitor to the heater circuit. See the performance characteristic graphs to determine values.

SCHEMATIC DIAGRAMS

TYPICAL APPLICATIONS

FEATURES

- Trimmed Output $\pm 0.3\%$
- Low Drift—5ppm/ $^{\circ}\text{C}$ Typical
- Low Noise—3ppm (p-p)
- High Line Rejection
- Temperature Output—REF-02
- Low Supply Current 1.4mA Max.

APPLICATIONS

- A to D and D to A Converters
- Precision Regulators
- Constant Current Sources
- V to F Converters
- Bridge Excitation

DESCRIPTION

The REF-01/REF-02 are precision 10V and 5V bandgap references which provide stable output voltages over a wide range of operating conditions. Output voltage is accurate to $\pm 0.3\%$ with a low 5ppm/ $^{\circ}\text{C}$ typical temperature coefficient. The REF-01 and REF-02 are excellent choices for applications where low drift, moderate accuracy, low power consumption and low cost are considerations.

The REF-02 includes a temperature output pin which provides a linear voltage proportional to absolute temperature.

For lower drift and higher accuracy references, please see the LT1019 and LT1021 data sheets.

Ultra Linear Strain Gauge Amplifier

*REDUCES REFERENCE AND AMPLIFIER LOADING TO ≈ 0 .

**IF $R6 = R3$, BRIDGE IS NOT LOADED BY $R2$ AND $R4$.

	Temperature Voltage Output Temperature Coefficient	(Note 2) REF-02	●	—	2.1	—	—	2.1	—	mV/ $^{\circ}C$

Note 1: Line and load regulation specifications include the effect of self heating.

Note 2: Limit current in or out of pin 3 to 50nA and capacitance on pin 3 to 30pF.

Note 3: ΔV is defined as the absolute difference between the maximum output voltage and the minimum output voltage over the specified temperature range expressed as a percentage of nominal output.

$$\Delta V = \left| \frac{V_{MAX} - V_{MIN}}{V_{OUT}} \right| \times 100$$

Note 4: ΔV specification applies trimmed or untrimmed.

Note 5: TC is defined as ΔV divided by the temperature range, i.e.,

$$TC = \frac{\Delta V}{T_{MAX} - T_{MIN}}$$

Note 6: 0.1Hz to 10Hz noise cannot be 100% tested on modern high speed test equipment, so Linear Technology does not put a guaranteed maximum specification on this parameter for standard units. 100% bench testing of 0.1Hz to 10Hz noise is available on special request. To ensure low output noise, Linear Technology *does* 100% test 10Hz to 1kHz noise. Consult factory for details.

FEATURES

- Pin-Compatible with LM111 Series Devices
- *Guaranteed* Max. 0.5mV Input Offset Voltage
- *Guaranteed* Max. 25nA Input Bias Current
- *Guaranteed* Max. 3nA Input Offset Current
- *Guaranteed* Max. 250ns Response Time
- *Guaranteed* Min. 200,000 Voltage Gain
- 50mA Output Current Source or Sink
- $\pm 30V$ Differential Input Voltage
- Fully Specified for Single +5V Operation

APPLICATIONS

- SAR A to D Converters
- Voltage to Frequency Converters
- Precision R/C Oscillator
- Peak Detector
- Motor Speed Control
- Pulse Generator
- Relay/Lamp Driver

DESCRIPTION

The LT1011 is a general purpose comparator with significantly better input characteristics than the LM111. Although pin-compatible with the LM111, it offers four times lower bias current, six times lower offset voltage, and five times higher voltage gain. Offset voltage drift—a previously unspecified parameter—is guaranteed at $15\mu V/^{\circ}C$. Additionally, the supply current is lower by a factor of two with no loss in speed. The LT1011 is several times faster than the LM111 when subjected to large overdrive conditions. It is also fully specified for DC parameters and response time when operating on a single +5V supply. These parametric improvements allow the LT1011 to be used in high accuracy (≥ 12 -bit) systems without trimming. In a 12-bit A to D application, for instance, using a 2mA DAC, the offset error introduced by the LT1011 is less than 1/2 LSB. The LT1011 retains all the versatile features of the LM111, including single 3V to $\pm 18V$ supply operation, and a floating transistor output with 50mA source/sink capability. It can drive loads referenced to ground, negative supply or positive supply, and is specified up to 50V between V^- and the collector output. A differential input voltage up to the full supply voltage is allowed, even with $\pm 18V$ supplies, enabling the inputs to be clamped to the supplies with simple diode clamps.

*Indicates parameters which are guaranteed for all supply voltages, including a single 5V supply. See Note 4.

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: Inputs may be clamped to supplies with diodes so that maximum input voltage actually exceeds supply voltage by one diode drop. See Input Protection in applications section.

Note 2: $T_J \text{ max} = 150^\circ\text{C}$ for the LT1011AM/LT1011M and 95°C for the LT1011AC/LT1011C.

Note 3: Output is sinking 1.5mA with $V_{OUT} = 0\text{V}$.

Note 4: These specifications apply for all supply voltages from a single +5V to $\pm 15\text{V}$, the entire input voltage range, and for both high and low output states. The high state is $I_{SINK} \geq 100\mu\text{A}$, $V_{OUT} \geq (V^+ - 1\text{V})$ and the low state is $I_{SINK} \leq 8\text{mA}$, $V_{OUT} \leq 0.8\text{V}$. Therefore, this specification defines a worst-case error band that includes effects due to common-mode signals, voltage gain, and output load.

Note 5: Drift is calculated by dividing the offset voltage difference measured at min and max temperatures by the temperature difference.

Note 6: Response time is measured with a 100mV step and 5mV overdrive. The output load is a 500 Ω resistor tied to +5V. Time measurement is taken when the output crosses 1.4V.

Note 7: Do not short the strobe pin to ground. It should be current driven at 3mA to 5mA for the shortest strobe time. Currents as low as 500 μA will strobe the LT111A if speed is not important. External leakage on the strobe pin in excess of 0.2 μA when the strobe is "off" can cause offset voltage shifts.

Note 8: See graph, Input Offset Voltage vs Common-Mode Voltage.

APPLICATIONS INFORMATION

Preventing Oscillation Problems

Oscillation problems in comparators are nearly always caused by stray capacitance between the output and inputs or between the output and other sensitive pins on the comparator. This is especially true with high gain-bandwidth comparators like the LT1011, which are designed for fast switching with millivolt input signal levels. The gain-bandwidth product of the LT1011 is over 10GHz. Oscillation problems tend to occur at frequencies around 5MHz, where the LT1011 has a gain of ≈ 2000 . This implies that attenuation of output signals must be at least 2000:1 at 5MHz as measured at the inputs. If the source impedance is $1k\Omega$, the effective stray capacitance between output and input must have a reactance of more than (2000) ($1k\Omega$) = $2M\Omega$, or less than $0.02pF$. The actual interlead capacitance between input and output pins on the LT1011 is less than $0.002pF$ when cut to printed circuit mount length. Additional stray capacitance due to printed circuit traces must be minimized by routing the output trace directly away from input lines and, if possible, running ground traces next to input traces to provide shielding. Additional steps to ensure oscillation-free operation are:

1. Bypass the strobe/balance pins with a $0.01\mu F$ capacitor connected from pin 5 to pin 6. This eliminates stray capacitive feedback from the output to the balance pins, which are nearly as sensitive as the inputs.
2. Bypass the negative supply (pin 4) with a $0.1\mu F$ ceramic capacitor close to the comparator. $0.1\mu F$ can also be used for the positive supply (pin 8) if the pull-up load is tied to a separate supply. When the pull-up load is tied directly to pin 8, use a $2\mu F$ solid tantalum bypass capacitor.
3. Bypass any slow moving or DC input with a capacitor ($\geq 0.01\mu F$) close to the comparator to reduce high frequency source impedance.
4. Keep resistive source impedance as low as possible. If a resistor is added in series with one input to balance source impedances for DC accuracy, bypass it with a capacitor. The low input bias current of the

LT1011 usually eliminates any need for source resistance balancing. A $5k\Omega$ imbalance, for instance, will create only $0.25mV$ DC offset.

5. Use hysteresis. This consists of shifting the input offset voltage of the comparator when the output changes state. Hysteresis forces the comparator to move quickly through its linear region, eliminating oscillations by "overdriving" the comparator under all input conditions. Hysteresis may be either AC or DC. AC techniques do not shift the apparent offset voltage of the comparator, but require a *minimum* input signal slew rate to be effective. DC hysteresis works for all input slew rates, but creates a shift in offset voltage dependent on the previous condition of the input signal. The circuit shown below is an excellent compromise between AC and DC hysteresis.

Comparator with Hysteresis

This circuit is especially useful for general purpose comparator applications because it does not force any signals directly back onto the input signal source. Instead, it takes advantage of the unique properties of the balance pins to provide extremely fast, clean output switching even with low frequency input signals in the millivolt range. The $0.003\mu F$ capacitor from pin 6 to pin 8 generates AC hysteresis because the voltage on the balance pins shifts slightly, depending on the state of the output. Both pins move about $4mV$. If one pin (6) is bypassed, AC hysteresis is created. It is only a few millivolts referred to the inputs, but is sufficient to switch the output at nearly the maximum speed of which the comparator is capable. To prevent

APPLICATIONS INFORMATION

problems from low values of input slew rate, a slight amount of DC hysteresis is also used. The sensitivity of the balance pins to current is about 0.5mV input referred offset for each microampere of balance pin current. The 15mΩ resistor tied from output to pin 5 generates 0.5mV DC hysteresis. The combination of AC and DC hysteresis creates clean oscillation-free switching with very small input errors. The curve below plots input referred error versus switching frequency for the circuit as shown.

Input Offset Voltage vs Time to Last Transition

Note that at low frequencies, the error is simply the DC hysteresis, while at high frequencies, an additional error is created by the AC hysteresis. The high frequency error can be reduced by reducing C_H , but lower values may not provide clean switching with very low slew rate input signals.

Input Protection

The inputs to the LT1011 are particularly suited to general purpose comparator applications because large differential and/or common-mode voltages can be tolerated without damage to the comparator. Either or both inputs can be raised 40V above the negative supply, independent of the positive supply voltage. Internal forward biased diodes will conduct when the inputs are taken below the

negative supply. In this condition, input current must be limited to 1mA. If very large (fault) input voltages must be accommodated, series resistors and clamp diodes should be used (see drawing below).

Limiting Fault Input Currents

The input resistors should limit fault current to a reasonable value (0.1mA to 20mA). Power dissipation in the resistors must be considered for continuous faults, especially when the LT1011 supplies are off. And one final caution: lightly loaded supplies may be forced to higher voltages by large fault currents flowing through D1-D4.

R3 and R4 limit input current to the LT1011 to less than 1mA when the input signals are held below V^- . They may be eliminated if R1 and R2 are large enough to limit fault current to less than 1mA.

Input Slew Rate Limitations

The response time of a comparator is typically measured with a 100mV step and a 5mV-10mV overdrive. Unfortunately, this does not simulate many real-world situations where the step size is typically much larger and overdrive can be significantly less. In the case of the LT1011, step size is important because the slew rate of internal nodes will limit response time for input step sizes larger than 1V. At 5V step size, for instance, response time increases from 150ns to 360ns. See the curve labeled Response Time vs Input Step Size for more detail.

APPLICATIONS INFORMATION

If response time is critical and large input signals are expected, clamp diodes across the inputs are recommended. The slew rate limitation can also affect performance when differential input voltage is low, but both inputs must slew quickly. Maximum suggested common-mode slew rate is $10V/\mu s$.

Strobing

The LT1011 can be strobed by pulling current out of the strobe pin. The output transistor is forced to an "off" state, giving a "hi" output at the collector (pin 7). Currents as low as $250\mu A$ will cause strobing, but at low strobe currents strobe delay will be 200ns–300ns. If strobe current is increased to 3mA, strobe delay drops to about 60ns. The voltage at the strobe pin is about 150mV below V^+ at zero strobe current and about 2V below V^+ for 3mA strobe current. *Do not ground the strobe pin. It must be current driven.* The drawing below shows a typical strobe circuit.

Typical Strobe Circuit

Note that there is no bypass capacitor between pins 5 and 6. This maximizes strobe speed, but leaves the comparator more sensitive to oscillation problems for slow, low level inputs. A 1pF capacitor between the output and pin 5 will greatly reduce oscillation problems without reducing strobe speed.

DC hysteresis can also be added by placing a resistor from output to pin 5. See step number 5 under "Preventing Oscillation Problems".

The pin (6) used for strobing is also one of the offset adjust pins. Current flow into or out of pin 6 must be kept very low ($<0.2\mu A$) when not strobing to prevent input offset voltage shifts.

Output Transistor

The LT1011 output transistor is truly floating in the sense that no current flows into or out of either the collector or emitter when the transistor is in the "off" state. The equivalent circuit is shown in the drawing below.

Output Transistor Circuitry

In the "off" state, I_1 is switched off and both Q1 and Q2 turn off. The collector of Q2 can be now held at any voltage above V^- without conducting current, including voltages above the positive supply level. Maximum voltage above V^- is 50V for the LT1011 and 40V for the LT1011C. The emitter can be held at any voltage between V^+ and V^- as long as it is negative with respect to the collector.

In the "on" state, I_1 is connected, turning on Q1 and Q2. Diodes D1 and D2 prevent deep saturation of Q2 to improve speed and also limit the drive current of Q1. The $R1/R2$ divider sets the saturation voltage of Q2 and provides turn-off drive. Either the collector or emitter pin can be held at a voltage between V^+ and V^- . This allows the remaining pin to drive the load. In typical applications, the emitter is connected to V^- or ground and the collector drives a load tied to V^+ or a separate positive supply.

APPLICATIONS INFORMATION

When the emitter is used as the output, the collector is typically tied to V^+ and the load is connected to ground or V^- . Note that the emitter output is phase reversed with respect to the collector output so that the "+" and "-" input designations must be reversed. When the collector is tied to V^+ , the voltage at the emitter in the "on" state is about 2V below V^+ (see curves).

Input Signal Range

The common-mode input voltage range of the LT1011 is about 300mV above the negative supply and 1.5V below

the positive supply, independent of the actual supply voltages (see curve in typical performance characteristics). This is the voltage range over which the output will respond correctly when the common-mode voltage is applied to one input and a higher or lower signal is applied to the remaining input. *If one input is inside the common-mode range and one is outside, the output will be correct. If the inputs are outside the common-mode range in opposite directions, the output will still be correct. If both inputs are outside the common-mode range in the same direction, the output will not respond to the differential input; it will remain unconditionally high (collector output).*

FEATURES

- Ultra Fast (10ns typ)
- Operates Off **Single** +5V Supply, or $\pm 5V$
- Complementary Output to TTL
- Low Offset Voltage
- No Minimum Input Slew Rate Requirement
- No Power Supply Current Spiking
- Output Latch Capability

APPLICATIONS

- High Speed A to D Converters
- High Speed Sampling Circuits
- Line Receiver
- Extended Range V to F Converters
- Fast Pulse Height/Width Discriminators

DESCRIPTION

The LT1016 is an ultra fast (10ns) comparator specifically designed to interface directly to TTL logic while operating off either a dual $\pm 5V$ supply or a single +5V supply. Tight offset voltage specifications and high gain allow the LT1016 to be used in precision applications. Matched complementary outputs further extend the versatility of this new comparator.

A unique output stage is featured on the LT1016. It provides active drive in both directions for maximum speed into TTL logic or passive loads, yet does not exhibit the large current spikes normally found in "totem pole" output stages. This eliminates the need for a minimum input slew rate typical of other very fast comparators. The ability of the LT1016 to remain stable with the outputs in the active region greatly reduces the problem of output "glitching" when the input signal is slow moving or is low level.

The LT1016 has a true latch pin for retaining input data at the outputs. The outputs will remain latched as long as the latch pin is held high. Quiescent negative power supply current is only 3mA—about ten times lower than competitive units. This reduces die temperature and allows the negative supply pin to be driven from virtually any supply voltage with a simple resistive divider. Device performance is not affected by variations in negative supply voltage.

APPLICATIONS INFORMATION

Common-Mode Considerations

The LT1016 is specified for a common-mode range of -3.75V to $+3.5\text{V}$ with supply voltages of $\pm 5\text{V}$. A more general consideration is that the common-mode range is 1.25V above the negative supply and 1.5V below the positive supply, independent of the actual supply voltage. The criteria for common-mode limit is that the output still responds correctly to a small differential input signal. Either input may be outside the common-mode limit (up to the supply voltage) as long as the remaining input is within the specified limit, and the output will still respond correctly. There is one consideration, however, for inputs which exceed the positive common-mode limit. Propagation delay will be increased by up to 10ns if the signal input is more positive than the upper common-mode limit and then switches back to within the common-mode range. This effect is not seen for signals more negative than the lower common-mode limit.

Input Impedance and Bias Current

Input bias current is measured with the output held at 1.4V . As with any simple NPN differential input stage, the LT1016 bias current will go to zero on an input which is low and double on the input which is high. If both inputs are less than 0.8V above V^- , both input bias currents will go to zero. If either input exceeds the positive

common-mode limit, input bias current will increase rapidly, approaching several milliamperes at $V_{IN} = V^+$.

Differential input resistance at zero differential input voltage is about $10\text{k}\Omega$, rapidly increasing as larger DC differential input signals are applied. Common-mode input resistance is about $4\text{M}\Omega$ with zero differential input voltage. With large differential input signals, the high input will have an input resistance of about $2\text{M}\Omega$ and the low input, greater than $20\text{M}\Omega$.

Input capacitance is typically 3.5pF . This is measured by inserting a $1\text{k}\Omega$ resistor in series with the input and measuring the resultant change in propagation delay.

Latch Pin Dynamics

The latch pin is intended to retain input data (output latched) when the latch pin goes high. This pin will float to a high state when disconnected, so a flow-through condition requires that the latch pin be grounded. To guarantee data retention, the input signal must be valid at least 5ns before the latch goes high (set-up time) and must remain valid at least 3ns after the latch goes high (hold time). When the latch goes low, new data will appear at the output in approximately $8\text{--}10\text{ns}$. The latch pin is designed to be driven with TTL or CMOS gates. It has no built-in hysteresis.

APPLICATIONS INFORMATION

Measuring Response Time

The LT1016 is able to respond quickly to fast low level signals because it has a very high gain-bandwidth product ($\approx 50\text{GHz}$), even at very high frequencies. To properly measure the response of the LT1016 requires an input signal source with very fast rise times and exceptionally clean settling characteristics. This last requirement comes about because the standard comparator test calls for an input step size that is large compared to the overdrive amplitude. Typical test conditions are 100mV step size with only 5mV overdrive. This requires an input signal that settles to within 1% (1mV) of final value in only a few nanoseconds with no ringing or "long tailing". Ordinary high speed pulse generators are not capable of generating such a signal, and in any case, no ordinary oscilloscope is capable of displaying the waveform to check its fidelity. Some means must be used to inherently generate a fast, clean edge with known final value.

The circuit shown in Figure 1 is the best *electronic* means of generating a known fast, clean step to test comparators. It uses a very fast transistor in a common base configuration. The transistor is switched "off" with a fast edge from the generator and the collector voltage settles to exactly 0V in just a few nanoseconds. The most important feature of this circuit is the lack of feedthrough from the generator to the comparator input. This prevents overshoot on the comparator input which would give a false fast reading on comparator response time.

To adjust this circuit for exactly 5mV overdrive, V_1 is adjusted so that the LT1016 output under test settles to

1.4V (in the linear region). Then V_1 is *changed* 5V to set overdrive at 5mV.

The test circuit shown measures low to high transition on the "+" input. For opposite polarity transitions on the output, simply reverse the inputs of the LT1016.

High Speed Design Techniques

A substantial amount of design effort has made the LT1016 relatively easy to use. It is much less prone to oscillation and other vagaries than some slower comparators, even with slow input signals. In particular, the LT1016 is stable in its linear region, a feature no other high speed comparator has. Additionally, output stage switching does not appreciably change power supply current, further enhancing stability. These features make the application of the 50GHz gain-bandwidth LT1016 considerably easier than other fast comparators. Unfortunately, laws of physics dictate that the circuit *environment* the LT1016 works in must be properly prepared. The performance limits of high speed circuitry are often determined by parasitics such as stray capacitance, ground impedance, and layout. Some of these considerations are present in digital systems where designers are comfortable describing bit patterns and memory access times in terms of nanoseconds. The LT1016 can be used in such fast digital systems and Figure 2 shows just how fast the device is. The simple test circuit allows us to see that the LT1016's (Trace B)

APPLICATIONS INFORMATION

response to the pulse generator (Trace A) is as fast as a TTL inverter (Trace C) even when the LT1016 has only millivolts of input signal! Linear circuits operating with this kind of speed make many engineers justifiably wary. Nanosecond domain linear circuits are widely associated with oscillations, mysterious shifts in circuit characteristics, unintended modes of operation and outright failure to function.

Other common problems include different measurement results using various pieces of test equipment, inability to make measurement connections to the circuit without inducing spurious responses and dissimilar operation between two "identical" circuits. If the components used in the circuit are good and the design is sound, all of the above problems can usually be traced to failure to provide a proper circuit "environment." To learn how to do this requires studying the causes of the aforementioned difficulties.

By far the most common error involves power supply bypassing. Bypassing is necessary to maintain low supply impedance. DC resistance and inductance in supply wires and PC traces can quickly build up to unacceptable levels. This allows the supply line to move as internal cur-

rent levels of the devices connected to it change. This will almost always cause unruly operation. In addition, several devices connected to an unbypassed supply can "communicate" through the finite supply impedances, causing erratic modes. Bypass capacitors furnish a simple way to eliminate this problem by providing a local reservoir of energy at the device. The bypass capacitor acts like an electrical flywheel to keep supply impedance low at high frequencies. The choice of what type of capacitors to use for bypassing is a critical issue and should be approached carefully. An unbypassed LT1016 is shown responding to a pulse input in Figure 3. The power supply the LT1016 sees at its terminals has high impedance at high frequency. This impedance forms a voltage divider with the LT1016, allowing the supply to move as internal conditions in the comparator change. This causes local feedback and oscillation occurs. Although the LT1016 responds to the input pulse, its output is a blur of 100MHz oscillation. *Always use bypass capacitors.*

In Figure 4 the LT1016's supplies are bypassed, but it still oscillates. In this case, the bypass units are either too far from the device or are lossy capacitors. *Use capacitors with good high frequency characteristics and mount*

Figure 2. LT1016 vs a TTL Gate

Figure 3. Unbypassed LT1016 Response

Figure 4. LT1016 Response with Poor Bypassing

APPLICATIONS INFORMATION

them as close as possible to the LT1016. An inch of wire between the capacitor and the LT1016 can cause problems. If operation in the linear region is desired, the LT1016 must be over a ground plate with good RF bypass capacitors ($\geq 0.01\mu\text{F}$) having lead lengths less than 0.2 inches. Do not use sockets.

In Figure 5 the device is properly bypassed but a new problem pops up. This photo shows both outputs of the comparator. Trace A appears normal, but Trace B shows an excursion of almost 8V — quite a trick for a device running from a +5V supply. This is a commonly reported problem in high speed circuits and can be quite confusing. It is not due to suspension of natural law, but is traceable to a grossly miscompensated or improperly selected oscilloscope probe. Use probes which match your oscilloscope's input characteristics and compensate them properly. Figure 6 shows another probe-induced problem. Here, the amplitude seems correct but the 10ns response time LT1016 appears to have 50ns edges! In this case, the

probe used is too heavily compensated or slow for the oscilloscope. Never use 1X or "straight" probes. Their bandwidth is 20MHz or less and capacitive loading is high. Check probe bandwidth to ensure it is adequate for the measurement. Similarly, use an oscilloscope with adequate bandwidth.

In Figure 7 the probes are properly selected and applied but the LT1016's output rings and distorts badly. In this case, the probe ground lead is too long. For general purpose work most probes come with ground leads about 6 inches long. At low frequencies this is fine. At high speed, the long ground lead looks inductive, causing the ringing shown. High quality probes are always supplied with some short ground straps to deal with this problem. Some come with very short spring clips which fix directly to the probe tip to facilitate a low impedance ground connection. For fast work, the ground connection to the probe should not exceed 1 inch in length. Keep the probe ground connection as short as possible.

Figure 5. Improper Probe Compensation Causes Seemingly Unexplainable Amplitude Error

Figure 6. Overcompensated or Slow Probes Make Edges Look Too Slow

Figure 7. Typical Results Due to Poor Probe Grounding

APPLICATIONS INFORMATION

Figure 8 shows the LT1016's output (Trace B) oscillating near 40MHz as it responds to an input (Trace A). Note that the input signal shows artifacts of the oscillation. This example is caused by improper grounding of the comparator. In this case, the LT1016's ground pin connection is 1 inch long. The ground lead of the LT1016 must be as short as possible and connected directly to a low impedance ground point. Any substantial impedance in the LT1016's ground path will generate effects like this. The reason for this is related to the necessity of bypassing the power supplies. The inductance created by a long device ground lead permits mixing of ground currents, causing undesired effects in the device. The solution here is simple. *Keep the LT1016's ground pin connection as short (typically 1/4 inch) as possible and run it directly to a low impedance ground. Do not use sockets.*

Figure 9 addresses the issue of the "low impedance ground," referred to previously. In this example, the output is clean except for chattering around the edges. This photograph was generated by running the LT1016 without a "ground plane." A ground plane is formed by using a continuous conductive plane over the surface of the cir-

cuit board. The only breaks in this plane are for the circuit's necessary current paths. The ground plane serves two functions. Because it is flat (AC currents travel along the surface of a conductor) and covers the entire area of the board, it provides a way to access a low inductance ground from anywhere on the board. Also, it minimizes the effects of stray capacitance in the circuit by referring them to ground. This breaks up potential unintended and harmful feedback paths. *Always use a ground plane with the LT1016, when input signal levels are low or slow moving.*

"Fuzz" on the edges is the difficulty in Figure 10. This condition appears similar to Figure 10, but the oscillation is more stubborn and persists well after the output has gone low. This condition is due to stray capacitive feedback from the outputs to the inputs. A 3k Ω input source impedance and 3pF of stray feedback allowed this oscillation. The solution for this condition is not too difficult. *Keep source impedances as low as possible, preferably 1k Ω or less. Route output and input pins and components away from each other.*

Figure 8. Excessive LT1016 Ground Path Resistance Causes Oscillation

Figure 9. Transition Instabilities Due to No Ground Plane

Figure 10. 3pF Stray Capacitive Feedback with 3k Ω Source Can Cause Oscillation

APPLICATIONS INFORMATION

The opposite of stray-caused oscillations appears in Figure 11. Here, the output response (Trace B) badly lags the input (Trace A). This is due to some combination of high source impedance and stray capacitance to ground at the input. The resulting RC forces a lagged response at the input, and output delay occurs. An RC combination of $2k\Omega$ source resistance and $10pF$ to ground gives a $20ns$ time constant — significantly longer than the LT1016's response time. *Keep source impedances low and minimize stray input capacitance to ground.*

Figure 12 shows another capacitance-related problem. Here the output does not oscillate, but the transitions are discontinuous and relatively slow. The villain of this situation is a large output load capacitance. This could be caused by cable driving, excessive output lead length or the input characteristics of the circuit being driven. In most situations this is undesirable and may be eliminated by buffering heavy capacitive loads. In a few cir-

cumstances it may not affect overall circuit operation and is tolerable. *Consider the comparator's output load characteristics and their potential effect on the circuit. If necessary, buffer the load.*

Another output-caused fault is shown in Figure 13. The output transitions are initially correct but end in a ringing condition. The key to the solution here is the ringing. What is happening is caused by an output lead which is too long. The output lead looks like an unterminated transmission line at high frequencies and reflections occur. This accounts for the abrupt reversal of direction on the leading edge and the ringing. If the comparator is driving TTL this may be acceptable, but other loads may not tolerate it. In this instance, the direction reversal on the leading edge might cause trouble in a fast TTL load. *Keep output lead lengths short. If they get much longer than a few inches, terminate with a resistor (typically 250Ω – 400Ω).*

Figure 11. Stray $5pF$ Capacitance from Input to Ground Causes Delay

Figure 12. Excessive Load Capacitance Forces Edge Distortion

Figure 13. Lengthy, Unterminated Output Lines Ring from Reflections

APPLICATIONS INFORMATION

Each time the circuit produces an output pulse, it feeds back a fixed quantity of charge (Q) to a summing node (Σ). The circuit's input furnishes a comparison current at the summing node. The difference signal at the node is integrated in a monitoring amplifier's feedback capacitor. The amplifier controls the circuit's output pulse generator, completing a feedback loop around the integrating amplifier. To maintain the summing node at zero, the pulse generator runs at a frequency which

permits enough charge pumping to offset the input signal. Thus, the output frequency will be linearly related to the input voltage. A1 is the integrating amplifier.

To trim this circuit, ground the input and adjust the 1k pot for 1Hz output. Next, apply 10.000V and set the 2k Ω unit for 10.000MHz output. The transfer linearity of the circuit is 0.06%. Full-scale drift is typically 50ppm/ $^{\circ}$ C and zero point error about 0.2 μ V/ $^{\circ}$ C (0.2Hz/ $^{\circ}$ C).

APPENDIX A

About Level Shifts

The TTL output of the LT1016 will interface with many circuits directly. Many applications, however, require some form of level shifting of the output swing. With LT1016-based circuits this is not trivial because it is desirable to maintain very low delay in the level shifting stage. When designing level shifters, keep in mind that the TTL output of the LT1016 is a sink-source pair (Figure A1) with good ability to drive capacitance (such as feedforward capacitors).

Figure A2 shows a non-inverting voltage gain stage with a 15V output. When the LT1016 switches, the base-emitter voltages at the 2N2369 reverse, causing it to switch very quickly. The 2N3866 emitter-follower gives a low im-

pedance output and the Schottky diode aids current sink capability.

Figure A3 is a very versatile stage. It features a bipolar swing which may be programmed by varying the output transistor's supplies. This 3ns delay stage is ideal for driving FET switch gates. Q1, a gated current source, switches the Baker-clamped output transistor, Q2. The heavy feedforward capacitor from the LT1016 is the key to low delay, providing Q2's base with nearly ideal drive. This capacitor loads the LT1016's output transition (Trace A, Figure A4), but Q2's switching is clean (Trace B, Figure A4) with 3ns delay on the rise and fall of the pulse.

Figure A1

Figure A2

APPENDIX A

Figure A5 is similar to A2 except that a sink transistor has replaced the Schottky diode. The two emitter-followers drive a power MOSFET which switches 1A at 15V. Most of the 7ns–9ns delay in this stage occurs in the MOSFET and the 2N2369.

When designing level shifters, remember to use transistors with fast switching times and high f_T 's. To get the kind of results shown, switching times in the ns range and f_T 's approaching 1GHz are required.

LT319AH LM319H	85°C	150°C/W	45°C/W

FEATURES

- Maximum Offset Voltage 1mV
- Maximum Bias Current 15nA
- Typical Output Drive 70mA
- Operates from 1.1V to 40V
- Internal Pull-Up Current
- Output Can Drive Loads Above V^+
- 30 μ A Supply Current (LT1017)
- 110 μ A Supply Current (LT1018)

APPLICATIONS

- Power Supply Monitors
- Relay Driving
- Oscillators

DESCRIPTION

The LT1017 and LT1018 are general purpose micropower comparators. The LT1017 is optimized for lowest operating power while the LT1018 operates at higher power and higher speed. Both devices can operate from a single 1.1V cell up to 40V. The output stage includes a class "B" pull-up current source, eliminating the need for an external resistive pull-up and saving power. The output stage is also designed to allow driving loads connected to a supply more positive than the device, as can comparators with open collector output stages.

Input specifications are also excellent. On-chip trimming minimizes offset voltage, while high gain and common-mode rejection ratio keep other input-referred errors low. Common-mode voltage range includes ground. Special circuitry prevents false output states even if the input is overdriven.

The LT1017 and LT1018 are pin compatible with older dual comparators such as 393 type devices.

- *Guaranteed* Max. Tracking Error between Input Pairs $\pm 0.1\%$
- Input Common-Mode Range to Both Supply Rails
- TTL/CMOS Compatible with ± 5 V or Single +5V Supply
- Input Errors are Stable with Time and Temperature

APPLICATIONS

- Battery Powered Systems
- Remote Sensing
- Window Comparator
- BANG-BANG Controllers

DESCRIPTION

The LTC1040 is a monolithic CMOS dual comparator manufactured using Linear Technology's enhanced LTCMOSTM silicon gate process. Extremely low operating power levels are achieved by internally switching the comparator ON for short periods of time. The CMOS output logic holds the output information continuously while not consuming any power.

In addition to switching power ON, a switched output is provided to drive external loads during the comparator's active time. This allows not only low comparator power, but low total system power.

Sampling is controlled by an external strobe input or an internal oscillator. The oscillator frequency is set by an external RC network.

Each comparator has a unique input structure, giving two differential inputs. The output of the comparator will be high if the algebraic sum of the inputs is positive and low if the algebraic sum of the inputs is negative.

BLOCK DIAGRAM

APPLICATIONS INFORMATION

The LTC1040 uses sampled data techniques to achieve its unique characteristics. Some of the experience acquired using classic linear comparators does not apply to this circuit, so a brief description of internal operation is essential to proper application.

The most obvious difference between the LTC1040 and other comparators is the dual differential input structure. Functionally, when the sum of inputs is positive, the comparator output is high and when the sum of the inputs is negative, the output is low. This unique input structure is achieved with CMOS switches and a precision capacitor array. Because of the switching nature of the inputs, the concept of input current and input impedance needs to be examined.

The equivalent input circuit is shown in Figure 1. Here, the input is being driven by a resistive source, R_S , with a bypass capacitor, C_S . The bypass capacitor may or may not be needed, depending on the size of the source resistance and the magnitude of the input voltage, V_{IN} .

Figure 1. Equivalent Input Circuit

For $R_S < 10k\Omega$

Assuming C_S is zero, the input capacitor, C_{IN} , charges to V_{IN} with a time constant of $R_S C_{IN}$. When R_S is too large, C_{IN} does not have a chance to fully charge during the sampling interval ($\approx 80\mu s$) and errors will result. If R_S exceeds $10k\Omega$ a bypass capacitor is necessary to minimize errors.

For $R_S > 10k\Omega$

For R_S greater than $10k\Omega$, C_{IN} cannot fully charge and a bypass capacitor, C_S , is needed. When switch $S1$ closes,

charge is shared between C_S and C_{IN} . The change in voltage on C_S because of this charge sharing is:

$$\Delta V = V_{IN} \times \frac{C_{IN}}{C_{IN} + C_S}$$

This represents an error and can be made arbitrarily small by increasing C_S .

With the addition of C_S a second error term caused by the finite input resistance of the LTC1040 must be considered. Switches $S1$ and $S2$ alternately open and close, charging and discharging C_{IN} between V_{IN} and ground. The alternate charge and discharge of C_{IN} causes a current to flow into the positive input and out of the negative input. The magnitude of this current is:

$$I_{IN} = q \times f_s = V_{IN} C_{IN} f_s$$

where f_s is the sampling frequency. Because the input current is directly proportional to input voltage, the LTC1040 can be said to have an average input resistance of:

$$R_{IN} = \frac{V_{IN}}{I_{IN}} = \frac{1}{f_s C_{IN}} = \frac{1}{f_s \times 33pF}$$

(see typical curve of R_{IN} vs f_s). A voltage divider is set up between R_S and R_{IN} causing error.

The input voltage error caused by these two effects is:

$$V_{ERROR} = V_{IN} \left(\frac{C_{IN}}{C_{IN} + C_S} + \frac{R_S}{R_S + R_{IN}} \right)$$

Example: $f_s = 10Hz$, $R_S = 1M\Omega$,
 $C_S = 1\mu F$, $V_{IN} = 1V$

$$V_{ERROR} = 1V \left(\frac{33 \times 10^{-12}}{1 \times 10^{-6}} + \frac{10^6}{10^6 + 3 \times 10^9} \right) \\ = 33\mu V + 330\mu V = 363\mu V$$

Notice that most of the error is caused by R_{IN} . If the sampling frequency is reduced to $1Hz$, the voltage error is reduced to $66\mu V$.

APPLICATIONS INFORMATION

Minimizing Comparison Errors

The two differential input voltages, V_1 and V_2 , are converted to charge by the input capacitors C_{IN1} and C_{IN2} (see Figure 2). The charge is summed at the virtual ground point and if the net charge is positive, the comparator output is high and if negative, it is low. There is an optimum way to connect these inputs, in a specific application, to minimize error.

Figure 2. Dual Differential Equivalent Input Circuit

Ignoring internal offset, the LTC1040 will be at its switch-point when:

$$V_1 \times C_{IN1} + V_2 \times C_{IN2} = 0.$$

Optimum error will be achieved when the differential voltages, V_1 and V_2 , are individually minimized. Figure 3 shows two ways to connect the LTC1040 to compare an input voltage, V_{IN} , to a reference voltage, V_{REF} . Using the above equation, each method will be at null when:

$$(a) (V_{REF} - 0V) C_{IN1} - (0V - V_{IN}) C_{IN2} = 0 \\ \text{or } V_{IN} = V_{REF} (C_{IN1} / C_{IN2})$$

$$(b) (V_{REF} - V_{IN}) C_{IN1} - (0V - 0V) C_{IN2} = 0 \\ \text{or } V_{IN} = V_{REF}.$$

Notice that in method (a) the null point depends on the ratio of C_{IN1} / C_{IN2} , but method (b) is independent of this ratio. Also, because method (b) has zero differential input voltage, the errors due to finite input resistance are negligible. The LTC1040 has a high accuracy capacitor array and even the non-optimum connection will only result in $\pm 0.1\%$ more error worst-case compared to the optimum connection.

Tracking Error

Tracking error is caused by the ratio error between C_{IN1} and C_{IN2} and is expressed as a percentage. For example, consider Figure 3(a) with $V_{REF} = 1V$. Then at null,

$$V_{IN} = V_{REF} \frac{C_{IN1}}{C_{IN2}} = 1V \pm 1mV$$

because C_{IN1} is guaranteed to equal C_{IN2} to within 0.1%.

(a) OK (b) Optimum

Figure 3. Two Ways to Do It

Common-Mode Range

The input switches of the LTC1040 are capable of switching to either the V^+ or V^- supply. This means that the input common-mode range includes both supply rails. Many applications, not feasible with conventional comparators, are possible with the LTC1040. In the load current detector shown in Figure 4, a 0.1Ω resistor is used to sense the current in the V^+ supply. This application requires the dual differential input and common-mode capabilities of the LTC1040.

Figure 4. Load Current Detector

APPLICATIONS INFORMATION

Offset Voltage Error

The errors due to offset, common-mode, power supply variation, gain and temperature are all included in the offset voltage specification. This makes it easy to compute the error when using the LTC1040.

Example: error comparison for Figure 4.

Assume: $2.8V \leq V_S \leq 6V$.

Then total worst-case error is:

$$I_{L(EROR)} = \pm (100mV \times 0.001 + 0.5mV) \times \frac{1A}{100mV} = \pm 6mA$$

Tracking Error V_{OS}

$$I_{L(EROR)}\% = \frac{6mA}{1A} \times 100 = \pm 0.6\%$$

Note: If source resistance exceeds $10k\Omega$, bypass capacitors should be used and the associated errors must be included.

Pulsed Power (V_{PP}) Output

It is often desirable to use comparators with resistive networks such as bridges. Because of the extremely low power consumption of the LTC1040, the power consumed by these resistive networks can far exceed that of the device itself.

At low sample rates the LTC1040 spends most of its time off. To take advantage of this, a pulsed power (V_{PP}) output is provided. V_{PP} is switched to V^+ when the comparator is on and to a high impedance (open circuit) when the comparator is off. The ON time is nominally $80\mu s$. Figure 5 shows the V_{PP} output circuit.

Figure 5. V_{PP} Output Switch

The V_{PP} output voltage is not precise (see V_{PP} Output Voltage versus Load Current curve). There are two ways V_{PP} can be used to power external networks without excessive errors: (1) ratiometric networks and (2) fast settling references.

In a ratiometric network (see Figure 6), the inputs are all proportional to V_{PP} . Consequently, for small changes, the absolute value of V_{PP} does not affect accuracy.

Figure 6. Ratiometric Network Driven by V_{PP}

It is critical that the inputs to the LTC1040 completely settle within $4\mu s$ of the start of the comparison cycle and that they do not change during the $80\mu s$ ON time. When driving resistive networks with V_{PP} , capacitive loading on the network should be minimized to meet the $4\mu s$ settling time requirement. It is not recommended that V_{PP} be used to drive networks with source impedances, as seen by the inputs, of greater than $10k\Omega$.

In applications where an absolute reference is required, the V_{PP} output can be used to drive a fast settling reference. The LT1009 2.5V reference, ideal in this application, settles in approximately $2\mu s$ (see Figure 7). The current through $R1$ must be large enough to supply the LT1009 minimum bias current ($\approx 1mA$) and the load current, I_L .

Figure 7. Driving Reference with V_{PP} Output

APPLICATIONS INFORMATION

Output Logic

In addition to the normal outputs (A_{OUT} and B_{OUT}), two additional outputs, $A+B$ and ON/OFF , are provided (see Figure 8 and Table I). All logic is powered from V^+ and ground, thus input and output logic levels are independent of the V^- supply. The LTC1040 is directly compatible with CMOS logic and is TTL compatible for $4.75V \leq V^+ \leq 5.25V$. No external pull-up resistors are required.

Table I. Output Logic Truth Table

ΣA INPUTS	ΣB INPUTS	A_{OUT}	B_{OUT}	$\overline{A+B}$	ON/OFF
+	+	H	H	L	L
+	-	H	L	L	L
-	+	L	H	L	H
-	-	L	L	H	I*

*I = indeterminate. When both A and B outputs are low, the ON/OFF output remains in the state it was in prior to entering $A_{OUT} = B_{OUT} = L$.

Using External Strobe

A positive pulse on the strobe input, with the OSC input tied to ground, will initiate a comparison cycle. The $STROBE$ input is edge-sensitive and pulse widths of 50ns will typically trigger the device.

Figure 8. LTC1040 Logic Diagram

Because of the sampling nature of the LTC1040, some sensitivity exists between the offset voltage and the falling edge of the input strobe. When the falling edge of the strobe signal falls within the comparator's active time ($80\mu s$ after rising edge), offset changes of as much as 2mV can occur. To eliminate this problem, make sure the strobe pulse width is greater than the response time, t_D .

Using Internal Strobe

An internal oscillator allows the LTC1040 to strobe itself. The frequency of oscillation, and hence sampling rate, is set by an external RC network (see typical curve of frequency versus R_{EXT} , C_{EXT}).

For self-oscillation, the $STROBE$ pin must be tied to ground. The external RC network is connected as shown in Figure 9.

To assure oscillation, R_{EXT} must be between 100k and 10M. There is no limit to the size of C_{EXT} .

R_{EXT} is very important in determining the power consumption. The average voltage at the oscillator pin is approximately $V^+ / 2$. The power consumed by R_{EXT} is then: $P_{REXT} = (V^+ / 2)^2 / R_{EXT}$.

Figure 9. External RC Connection

Example: $R_{EXT} = 1M$, $V^+ = 5V$, $P_{REXT} = (2.5)^2 / 10^6 = 6.25 \times 10^{-6}W$.

power is a premium R_{EXT} should be made as large as possible. Note that the power consumed by R_{EXT} is *not* a function of f_s or C_{EXT} .

TYPICAL APPLICATIONS

Window Comparator with Independent Window Limits and Fully Floating Differential Input

The LTC1040 as a Linear Amplifier

With a simple RC filter the LTC1040 can be made to function as a linear amplifier. By filtering the logic output and feeding it back to the negative input, the loop forces the output duty cycle $[t_{ON} / (t_{ON} + t_{OFF})]$ so that V_{OUT} equals V_{IN} (Figure 10).

The RC time constant is set to keep the ripple on the output small. The maximum output ripple is: $\Delta V = V^+ / f_s RC$ and

Figure 10. The LTC1040 as a Linear Amplifier

Hysteresis Comparator with Fully Floating Differential Input

$$OUT = '0' \text{ WHEN } V_{IN} > V_U = \frac{V_{TRIP} R_2 + (5V) R_1}{R_1 + R_2} = 0.996 V_{TRIP} + 20mV$$

$$OUT = '1' \text{ WHEN } V_{IN} < V_L = \frac{V_{TRIP} R_2}{R_1 + R_2} = 0.996 V_{TRIP}$$

* TO CENTER HYSTERESIS ABOUT V_{TRIP} FORCE THIS INPUT TO HYSTERESIS/2 (10mV)

should be set to 0.5mV to 1mV for best results. Notice that the higher the sampling frequency, f_s , the lower RC can be. This is important because the RC filter also sets the loop response. A convenient way to keep f_s as high as possible under all conditions is to connect a 100k resistor to pin 16 (OSC) with no capacitance to ground.

PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

J Package 18 Lead Hermetic DIP

N Package 18 Lead Plastic DIP

FEATURES

- Micropower 1.5 μ W (1 Sample/Second)
- Wide Supply Range 2.8V to 16V
- High Accuracy
 - Guaranteed SET POINT Error ± 0.5 mV Max.
 - Guaranteed Deadband $\pm 0.1\%$ of Value Max.
- Wide Input Voltage Range V^+ to Ground
- TTL Outputs with 5V Supply
- Two Independent Ground-Referenced Control Inputs
- Small Size 8-Pin MiniDIP

APPLICATIONS

- Temperature Control (Thermostats)
- Motor Speed Control
- Battery Charger
- Any ON-OFF Control Loop

DESCRIPTION

The LTC1041 is a monolithic CMOS BANG-BANG controller manufactured using Linear Technology's enhanced LTCMOSTM silicon gate process. BANG-BANG loops are characterized by turning the control element fully ON or fully OFF to regulate the average value of the parameter to be controlled. The SET POINT input determines the average control value and the DELTA input sets the deadband. The deadband is always $2 \times \text{DELTA}$ and is centered around the SET POINT. Independent control of the SET POINT and deadband, with no interaction, is made possible by the unique sampling input structure of the LTC1041.

An external RC connected to the OSC pin sets the sampling rate. At the start of each sample, internal power to the analog section is switched on for $\approx 80\mu$ s. During this time the analog inputs are sampled and compared. After the comparison is complete, power is switched off. This achieves extremely low average power consumption at low sampling rates. CMOS logic holds the output continuously while consuming virtually no power.

To keep system power at an absolute minimum, a switched power output (V_{PP}) is provided. External loads, such as bridge networks and resistive dividers, can be driven by this switched output.

The output logic sense (i.e., $\text{ON} = V^+$) can be reversed (i.e., $\text{ON} = \text{GND}$) by interchanging the V_{IN} and SET POINT inputs. This has no other effect on the operation of the LTC1041.

APPLICATIONS INFORMATION

The LTC1041 uses sampled data techniques to achieve its unique characteristics. It consists of two comparators, each of which has two differential inputs (Figure 1). When the sum of the voltages on a comparator's inputs is positive, the output is high and when the sum is negative, the output is low. The inputs are interconnected such that the RS flip-flop is reset ($ON/\overline{OFF} = GND$) when $V_{IN} > (SET\ POINT + \Delta)$ and is set ($ON/\overline{OFF} = V^+$) when $V_{IN} < (SET\ POINT - \Delta)$. This makes a very precise hysteresis loop of $2 \times \Delta$ centered around the SET POINT. See Figure 1(b).

For $R_S < 10k\Omega$

The dual differential input structure is made with CMOS switches and a precision capacitor array. Input impedance characteristics of the LTC1041 can be determined from the equivalent circuit shown in Figure 2. The input capacitance will charge with a time constant of $R_S \times C_{IN}$. The ability to fully charge C_{IN} from the signal source during the controller's active time is critical in determining errors caused by the input charging current. For source resistances less than $10k\Omega$, C_{IN} fully charges and no error is caused by the charging current.

Figure 1. LTC1041 Block Diagram

Figure 2. Equivalent Input Circuit

APPLICATIONS INFORMATION

For $R_S > 10k\Omega$

For source resistances greater than $10k\Omega$, C_{IN} cannot fully charge, causing voltage errors. To minimize these errors, an input bypass capacitor, C_S , should be used. Charge is shared between C_{IN} and C_S , causing a small voltage error. The magnitude of this error is $\Delta V = V_{IN} \times C_{IN} / (C_{IN} + C_S)$. This error can be made arbitrarily small by increasing C_S .

The averaging effect of the bypass capacitor, C_S , causes another error term. Each time the input switches cycle between the plus and minus inputs, C_{IN} is charged and discharged. The average input current due to this is $I_{AVG} = V_{IN} \times C_{IN} \times f_s$, where f_s is the sampling frequency. Because the input current is directly proportional to the differential input voltage, the LTC1041 can be said to have an average input resistance of $R_{IN} = V_{IN} / I_{AVG} = 1 / (f_s \times C_{IN})$.

Since two comparator inputs are connected in parallel, R_{IN} is one half of this value (see typical curve of R_{IN} versus f_s). This finite input resistance causes an error due to the voltage divider between R_S and R_{IN} .

The input voltage error caused by both of these effects is $V_{ERROR} = V_{IN} [2C_{IN} / (2C_{IN} + C_S) + R_S / (R_S + R_{IN})]$.

Example: assume $f_s = 10Hz$, $R_S = 1M$, $C_S = 1\mu F$, $V_{IN} = 1V$, $V_{ERROR} = 1V(66\mu V + 660\mu V) = 726\mu V$. Notice that most of the error is caused by R_{IN} . If the sampling frequency is reduced to $1Hz$, the voltage error from the input impedance effects is reduced to $136\mu V$.

Input Voltage Range

The input switches of the LTC1041 are capable of switching either to the V^+ supply or ground. Consequently, the input voltage range includes both supply rails. This is a further benefit of the sampling input structure.

Error Specifications

The only measurable errors on the LTC1041 are the deviations from "ideal" of the upper and lower switching levels [Figure 1(b)]. From a control standpoint, the error

in the SET POINT and deadband is critical. These errors may be defined in terms of V_U and V_L .

$$\text{SET POINT error} \equiv \left(\frac{V_U + V_L}{2} \right) - \text{SET POINT}$$

$$\text{deadband error} \equiv (V_U - V_L) - 2 \times \text{DELTA}$$

The specified error limits (see electrical characteristics) include error due to offset, power supply variation, gain, time and temperature.

Pulsed Power (V_{PP}) Output

It is often desirable to use the LTC1041 with resistive networks such as bridges and voltage dividers. The power consumed by these resistive networks can far exceed that of the LTC1041 itself.

At low sample rates the LTC1041 spends most of its time off. A switched power output, V_{PP} , is provided to drive the input network, reducing its average power as well. V_{PP} is switched to V^+ during the controller's active time ($\approx 80\mu s$) and to a high impedance (open circuit) when internal power is switched off.

Figure 3 shows the V_{PP} output circuit. The V_{PP} output voltage is not precisely controlled when driving a load (see typical curve of V_{PP} output voltage versus load current). In spite of this, high precision can be achieved in two ways: (1) driving ratiometric networks and (2) driving fast settling references.

Figure 3. V_{PP} Output Switch

APPLICATIONS INFORMATION

In ratiometric networks (Figure 4) all the inputs are proportional to V_{PP} . Consequently, the absolute value of V_{PP} does not affect accuracy.

Figure 4. Ratiometric Network Driven by V_{PP}

If the best possible performance is needed, the inputs to the LTC1041 must completely settle within $4\mu s$ of the start of the comparison cycle (V_{PP} high impedance to V^+ transition). Also, it is critical that the input voltages do not change during the $80\mu s$ active time. When driving resistive input networks with V_{PP} , capacitive loading should be minimized to meet the $4\mu s$ settling time requirement. Further, care should be exercised in layout when driving networks with source impedances, as seen by the LTC1041, of greater than $10k\Omega$ (see For $R_s > 10k\Omega$).

In applications where an absolute reference is required, the V_{PP} output can be used to drive a fast settling reference. The LTC1009 2.5V reference settles in $\approx 2\mu s$ and is ideal for this application (Figure 5). The current through $R1$ must be large enough to supply the LT1009 minimum bias current ($\approx 1mA$) and the load current, I_L .

Figure 5. Driving Reference with V_{PP} Output

Internal Oscillator

An internal oscillator allows the LTC1041 to strobe itself. The frequency of the oscillation, and hence the sampling rate, is set with an external RC network (see typical curve, OSC frequency versus R_{EXT} , C_{EXT}). R_{EXT} and C_{EXT} are connected as shown in Figure 1. To assure oscillation, R_{EXT} must be between $100k\Omega$ and $10M\Omega$. There is no limit to the size of C_{EXT} .

At low sampling rates, R_{EXT} is very important in determining the power consumption. R_{EXT} consumes power continuously. The average voltage at the OSC pin is approximately $V^+/2$, giving a power dissipation of $P_{REXT} = (V^+/2)^2 / R_{EXT}$.

Example: assume $R_{EXT} = 1M\Omega$, $V^+ = 5V$, $P_{REXT} = (2.5)^2 / 10^6 = 6.25\mu W$. This is approximately four times the power consumed by the LTC1041 at $V^+ = 5V$ and $f_s = 1$ sample/second. Where power is a premium, R_{EXT} should be made as large as possible. Note that the power dissipated by R_{EXT} is *not* a function of f_s or C_{EXT} .

If high sampling rates are needed and power consumption is of secondary importance, a convenient way to get the maximum possible sampling rate is to make $R_{EXT} = 100k\Omega$ and $C_{EXT} = 0$. The sampling rate, set by the controller's active time, will nominally be $\approx 10kHz$.

To synchronize the sampling of the LTC1041 to an external frequency source, the OSC pin can be driven by a CMOS gate. A CMOS gate is necessary because the input trip points of the oscillator are close to the supply rails and TTL does not have enough output swing. Externally driven, there will be a delay from the rising edge of the OSC input and the start of the sampling cycle of approximately $5\mu s$.

FEATURES

- Guaranteed Max Input Offset Voltage 1.0mV
- Guaranteed Max Input Offset Current 5nA
- Guaranteed Max Response Time 250ns
- Guaranteed Min. Voltage Gain 200,000
- $\pm 30V$ Differential Input Voltage
- Drives 50mA Loads At Up To 50V.
- $\frac{1}{2}$ The Power Dissipation For LT111A/LT311A

APPLICATIONS

- General Purpose Comparator
- Zero Crossing Detector
- Voltage To Frequency Converter

DESCRIPTION

The LT111A is an improved version of the LM111 general purpose comparator. These new devices offer maximum input offset voltage of 1.0mV and input offset current of 5.0nA with a maximum response time of 250ns. The LT111A operate from a single 5V supply to $\pm 15V$ supplies and can drive up to 50mA loads referred to ground or either supply. A separate output ground pin allows output signals to be isolated from analog ground.

The versatility of the LT111A is enhanced by an input stage design which allows differential input signals of up to $\pm 30V$. Offset balancing, strobe capability and the ability to "OR" the output is also included. These features plus Linear Technology Corporation's advanced processing and reliability enhancements make the LT111A an ideal choice for most comparator applications. For higher performance requirements, see the LT1011.

FEATURES

- Guaranteed max 0.5 mV input offset voltage
- Input Protection Diodes
- Operates from single 5V supply
- 25mA drive capability
- 80nS response time

APPLICATIONS

- Window detectors
- High speed one shot
- Relay/lamp drivers
- Voltage controlled oscillators

DESCRIPTION

The LT119A is an improved version of the LM119 dual comparator. It features lower input offset voltage and offset current, higher voltage gain, guaranteed common mode rejection, and input protection diodes.

The LT119A is capable of operation over a supply range from 5 Volts to ± 15 Volts and can drive 25mA loads from each open collector output. A separate ground pin allows the LT119A to isolate system grounds.

Linear Technology Corporation's advanced processing, design techniques and reliability make the LT119A/LT319A an ideal choice over previous devices in most comparator applications.

Window Detector*

*Allowed window for single +5V supply is 1.2V to 3.8V

● denotes the specifications which apply over the full operating temperature range.

The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

Note 1: For supply voltages less than $\pm 15V$, the maximum input voltage is equal to the supply voltage.

Note 2: Unless otherwise noted, supply voltage equals $\pm 15V$ and $T_A = 25^\circ C$. The ground pin is grounded. Note that the maximum voltage allowed between the ground pin and V^+ is 18V. Do not tie the ground pin to V^- when the power supply voltage exceeds $\pm 9V$. The offset voltage, offset current and bias current specifications apply for all supply voltages between $\pm 15V$ and $+5V$ unless otherwise specified.

Note 3: The offset voltages and currents given are the maximum values required to drive the output within 1 volt of either supply with a 1mA load — thus, these parameters define an error band and take into account the worst case effects of voltage gain and input impedance.

Note 4: Response time specified is for a 100mV input step with 5mV overdrive.

- Full Audio Frequency Filters
- Tracking Filters

TYPICAL APPLICATION

Wide Range 2nd Order Bandpass/Notch Filter with $Q=10$

DESCRIPTION

PROPRIETARY PRODUCTS

The LTC1054 is a high performance, low power, single supply, switched capacitor universal filter. It is designed to provide a wide range of filter characteristics, including bandpass, notch, allpass, and lowpass. The filter is characterized by its wide range of center frequencies, from 0.1Hz to 40kHz, and its high Q factor, up to 10. The filter is also characterized by its low power consumption, making it suitable for use in battery-powered applications. The filter is designed to provide a wide range of filter characteristics, including bandpass, notch, allpass, and lowpass. The filter is characterized by its wide range of center frequencies, from 0.1Hz to 40kHz, and its high Q factor, up to 10. The filter is also characterized by its low power consumption, making it suitable for use in battery-powered applications.

High Q characteristics of filter functions can be obtained by connecting the LTC1054 with the LTC1054A dual analog universal LTC1054 triple universal filter. Any electrical filter specification listed at Bunkerhill, Co., or Patent and Trademark Office is typical.

The LTC1054 can be operated with single or dual supplies ranging from $\pm 2.7V$ to $\pm 10V$ or $\pm 10V$ single supply and is almost completely CMOS compatible.

The LTC1054 is implemented by using Linear Technology's enhanced LTC1054TM silicon gate process.

High Performance Switched Capacitor Universal Filter

FEATURES

- All Filter Parameters *Guaranteed* over Temperature
- Wide Center Frequency Range (0.1Hz to 40kHz)
- Low Noise Wide Dynamic Range
- Guaranteed* Operation for $\pm 2.37V$ and $\pm 5V$ Supply
- Low Power Consumption
- Guaranteed* Clock to Center Frequency Accuracy of 0.3% (LTC1059A)
- Guaranteed* Low Offset Voltages over Temperature
- Very Low Center Frequency and Q Tempco
- Clock Input T²L or CMOS Compatible
- Separate Highpass (or Notch or Allpass), Bandpass, Lowpass Outputs

APPLICATIONS

- Sinewave Oscillators
- Sweepable Bandpass/Notch Filters
- Full Audio Frequency Filters
- Tracking Filters

DESCRIPTION

The LTC1059 consists of a general purpose, high performance, active filter building block and an uncommitted op amp. The filter building block together with an external clock and 2 to 5 resistors can produce various second order functions which are available at its three output pins. Two out of three always provide lowpass and bandpass functions while the third output pin can produce notch or highpass or allpass. The center frequency of these functions can be tuned from 0.1Hz to 40kHz and it is dependent on an external clock or an external clock and a resistor ratio. The filter can handle input frequencies up to 100kHz. The uncommitted op amp can be used to obtain additional allpass and notch functions, for gain adjustment or for cascading techniques.

Higher than second order filter functions can be obtained by cascading the LTC1059 with the LTC1060 dual universal filter or LTC1061 triple universal filter. Any classical filter realization (such as Butterworth, Cauer, Bessel and Chebyshev) can be formed.

The LTC1059 can be operated with single or dual supplies ranging from $\pm 2.37V$ to $\pm 8V$ (or 4.74V to 16V single supply) and is pinout compatible with MF5.

The LTC1059 is manufactured by using Linear Technology's enhanced LTCMOSTM silicon gate process.

LTCMOSTM is a trademark of Linear Technology Corp.

APPLICATIONS INFORMATION

The LTC1059 is compatible with the LTC1060. All the LTC1059 pins are functionally equivalent to the LTC1060 pins bearing the same title. For a detailed pin description and definition of various modes of operation refer to the LTC1060 data sheet. The LTC1059 is typically "faster" than the LTC1060 especially under single 5V (or $\pm 2.5V$)

supply operation. This becomes apparent through the typical performance characteristics of the part. All the graphs shown in this data sheet have been drawn under the same test conditions as in the LTC1060 data sheet; they are also numbered in the same order. For a complete discussion of the filter characteristics see the LTC1060 data sheet.

PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

J Package 14 Lead Hermetic DIP

N Package 14 Lead Plastic

Universal Dual Filter Building Block

FEATURES

- **Guaranteed** Filter Specification for $\pm 2.37V$ and $\pm 5V$ Supply
- Operates up to 30kHz
- Low Power and 88dB Dynamic Range at $\pm 2.5V$ Supply
- Center Frequency Q Product up to 1.6MHz
- **Guaranteed** Offset Voltages
- **Guaranteed** Clock to Center Frequency Accuracy over Temperature
 - 0.3% for LTC1060A
 - 0.8% for LTC1060
- **Guaranteed** Q Accuracy over Temperature
- Low Temperature Coefficient of Q and Center Frequency
- Low Crosstalk, 70dB
- Clock Inputs TTL and CMOS Compatible

APPLICATIONS

- Single 5V Supply Medium Frequency Filters
- Very High Q and High Dynamic Range Bandpass, Notch Filters
- Tracking Filters
- Telecom Filters

DESCRIPTION

The LTC1060 consists of two high performance, switched capacitor filters. Each filter, together with 2 to 5 resistors, can produce various 2nd order filter functions such as low-pass, bandpass, highpass notch and allpass. The center frequency of these functions can be tuned by an external clock, or by an external clock and resistor ratio. Up to 4th order full biquadratic functions can be achieved by cascading the two filter blocks. Any of the classical filter configurations (like Butterworth, Chebyshev, Bessel, Cauer) can be formed.

The LTC1060 operates with either a single or dual supply from $\pm 2.37\text{V}$ to $\pm 8\text{V}$. When used with low supply (i.e. single 5V supply), the filter typically consumes 12mW and can operate with center frequencies up to 10kHz . With $\pm 5\text{V}$ supply, the frequency range extends to 30kHz and very high Q values can also be obtained.

The LTC1060 is manufactured by using Linear Technology's enhanced LTCMOS™ silicon gate process. Because of this, low offsets, high dynamic range, high center frequency Q product and excellent temperature stability are obtained.

The LTC1060 is pinout compatible with MF10.

LTCMOS™ is a trademark of Linear Technology Corp.

PIN DESCRIPTIONS AND APPLICATIONS INFORMATION

Power Supplies

The V_A^+ and V_D^+ (pins 7 and 8) and the V_A^- , V_D^- (pins 14 and 13) are, respectively, the analog and digital positive and negative supply pins. For most cases, pins 7 and 8 should be tied together and bypassed by a $0.1\mu\text{F}$ disc ceramic capacitor. The same holds for pins 14 and 13. If the LTC1060 operates in high digital noise environment, the supply pins can be bypassed separately. Pins 7 and 8 are internally connected through the IC substrate and should be biased from the same DC source. Pins 14 and 13 should also be biased from the same DC source.

The LTC1060 is designed to operate with $\pm 2.5\text{V}$ supply (or single 5V) and with $\pm 5\text{V}$ to $\pm 8\text{V}$ supplies. The minimum supply, where the filter operates reliably, is $\pm 2.37\text{V}$. With low supply operation, the maximum input clock frequency is about 500kHz . Beyond this, the device exhibits excessive Q enhancement and center frequency errors.

Clock Input Pins and Level Shift

The level shift (LSH) pin 9 is used to accommodate T^2L or CMOS clock levels. With dual supplies equal or higher to $\pm 4.5\text{V}$, pin 9 should be connected to ground (same potential as the AGND pin). Under these conditions the clock levels can be T^2L or CMOS. With single supply operation, the negative supply pins and the LSH pin should be tied to the system ground. The AGND, pin 15, should be biased at $1/2$ supplies, as shown in the "Single 5V Gain of 1000 4th Order Bandpass Filter" circuit. Again, under these conditions, the clock levels can be T^2L or CMOS. The input clock pins (10, 11) share the same level shift pin. The clock logic threshold level over temperature is typically $1.5\text{V} \pm 0.1\text{V}$ above the LSH pin potential. The duty cycle of the input clock should be close to 50%. For clock frequencies below 1MHz , the (f_{CLK}/f_0) ratio is independent from the clock input levels and from its rise and fall times. Fast rising clock edges, however, improve the filter DC offsets. For clock frequencies above 1MHz , T^2L level clocks are recommended.

50/100/Hold (Pin 12)

By tying pin 12 to (V_A^+, V_D^+) , the filter operates in the 50:1 mode. With $\pm 5\text{V}$ supplies pin 12 can be typically 1V below the positive supply without affecting the 50:1 operation of

the device. By tying pin 12 to $1/2$ supplies (which should be the AGND potential), the LTC1060 operates in the 100:1 mode. The $1/2$ supply bias of pin 12 can vary around the $1/2$ supply potential without affecting the 100:1 filter operation. This is shown in Table 1.

When pin 12 is shorted to the negative supply pin, the filter operation is stopped and the bandpass and lowpass outputs act as a S/H circuit holding the last sample. The hold step is 20mV and the droop rate is $150\mu\text{V}/\text{second}$!

Table 1

Total Power Supply	Voltage Range of Pin 12 for 100:1 Operation
+ 5V	$2.5\text{V} \pm 0.5\text{V}$
+ 10V	$+5\text{V} \pm 1\text{V}$
+ 15V	$+7.5\text{V} \pm 1.5\text{V}$

S_{1A} , S_{1B} (Pins 5 and 16)

These are voltage signal input pins and, if used, they should be driven with a source impedance below $5\text{k}\Omega$. The S_{1A} , S_{1B} pins can be used to alter the CLK to center frequency ratio (f_{CLK}/f_0) of the filter (see Modes 1b, 1c, 2a, 2b) or to feedforward the input signal for allpass filter configurations (see Modes 4 and 5). When these pins are not used, they should be tied to the AGND pin.

$S_{A/B}$ (Pin 6)

When $S_{A/B}$ is high, the S_2 input of the filter's voltage summer (see Block Diagram) is tied to the lowpass output. This frees the S_1 pin to realize various modes of operation for improved applications flexibility. When the $S_{A/B}$ pin is connected to the negative supply, the S_2 input switches to ground and internally becomes inactive. This improves the filter noise performance and typically lowers the value of the offset V_{OS2} .

AGND (Pin 15)

This should be connected to the system ground for dual supply operation. When the LTC1060 operates with a single positive supply, the analog ground pin should be tied to $1/2$ supply and bypassed with a $0.1\mu\text{F}$ capacitor, as shown in the application, "Single 5V , Gain of 1000 4th Order Bandpass Filter". The positive inputs of all the internal op amps, as well as the reference point of all the internal

APPLICATIONS INFORMATION

switches are connected to the AGND pin. Because of this, a "clean" ground is recommended.

f_{CLK}/f_0 Ratio

The (f_{CLK}/f_0) reference of 100:1 or 50:1 is derived from the filter center frequency measured in mode 1, with a $Q=10$ and $V_S = \pm 5V$. The clock frequencies are, respectively, 500kHz/250kHz for the 100:1/50:1 measurement. All the curves shown in the Typical Performance Characteristics section are normalized to the above references.

Graphs 1 and 2 in the Typical Performance Characteristics show the (f_{CLK}/f_0) variation versus values of ideal Q . The LTC1060 is a sampled data filter and it only approximates continuous time filters. In this data sheet, the LTC1060 is treated in the frequency domain because this approximation is good enough for most filter applications. The LTC1060 deviates from its ideal continuous filter model when the (f_{CLK}/f_0) ratio decreases and when the Q 's are low. Since low Q filters are not selective, the frequency domain approximation is well justified. In graph 15 the LTC1060 is connected in mode 3 and its (f_{CLK}/f_0) ratio is adjusted to 200:1 and 500:1. Under these conditions, the filter is over-sampled and the (f_{CLK}/f_0) curves are nearly independent of the Q values. In mode 3, the (f_{CLK}/f_0) ratio typically deviates from the tested one in mode 1 by $\pm 0.1\%$.

$f_0 \times Q$ Product Ratio

This is a figure of merit of general purpose active filter building blocks. The $f_0 \times Q$ product of the LTC1060 depends on the clock frequency, the power supply voltages, the junction temperature and the mode of operation.

At 25°C ambient temperature for $\pm 5V$ supplies, and for clock frequencies below 1MHz, in mode 1 and its derivatives, the $f_0 \times Q$ product is mainly limited by the desired f_0 and Q accuracy. For instance, from graph 4 at 50:1 and for f_{CLK} below 800kHz a predictable ideal Q of 400 can be obtained. Under this condition, a respectable $f_0 \times Q$ product of 6.4MHz is achieved. The 16kHz center frequency will be about 0.22% off from the tested value at 250kHz clock (see graph 1). For the same clock frequency of 800kHz and for the same Q value of 400, the $f_0 \times Q$ product can be further increased if the clock to center frequency ratio is low-

ered below 50:1. In mode 1c with $R5=0$ and $R6=\infty$, the (f_{CLK}/f_0) ratio is $50/\sqrt{2}$. The $f_0 \times Q$ product can now be increased to 9MHz since, with the same clock frequency and same Q value, the filter can handle a center frequency of $16kHz \times \sqrt{2}$.

For clock frequencies above 1MHz, the $f_0 \times Q$ product is limited by the clock frequency itself. From graph 4 at $\pm 7.5V$ supply, 50:1, and 1.4MHz clock, a Q of 5 has about 8% error; the measured 28kHz center frequency was skewed by 0.8% with respect to the guaranteed value at 250kHz clock. Under these conditions, the $f_0 \times Q$ product is only 140kHz, but the filter can handle higher input signal frequencies than the 800kHz clock frequency-very high Q case described above.

Mode 3, Figure 11, and the modes of operation where $R4$ is finite, are "slower" than the basic mode 1. This is shown in graph 16 and 17. The resistor $R4$ places the input op amp inside the resonant loop. The finite GBW of this op amp creates an additional phase shift and enhances the Q value at high clock frequencies. Graph 16 was drawn with a small capacitor, C_C , placed across $R4$ and as such, at $V_S = \pm 5V$, the $(1/2\pi R4 C_C) = 2MHz$. With $V_S = \pm 2.5V$ the $(1/2\pi R4 C_C)$ should be equal to 1.4MHz. This allows the Q curve to be slightly "flatter" over a wider range of clock frequencies. If, at $\pm 5V$ supply, the clock is below 900kHz (or 400kHz for $V_S = \pm 2.5V$), this capacitor, C_C , is not needed.

For graph 25, the clock to center frequency ratios are altered to 70.7:1 and 35.35:1. This is done by using mode 1c with $R5=0$, Figure 7, or mode 2 with $R2=R4=10k\Omega$. The mode 1c, where the input op amp is outside the main loop, is much faster. Mode 2, however, is more versatile. At 50:1, and for $T_A = 25^\circ C$ the mode 1c can be tuned for center frequencies up to 30kHz.

Output Noise

The wideband rms noise of the LTC1060 outputs is nearly independent from the clock frequency provided that the clock itself does not become part of the noise. The LTC1060 noise slightly decreases with $\pm 2.5V$ supply. The noise at the BP and LP outputs increases for high Q 's. Table 2 shows typical values of wideband rms noise. The numbers in parentheses are the noise measurement in mode 1 with the $S_{A/B}$ pin shorted to V^- as shown in Figure 25.

APPLICATIONS INFORMATION

Table 2. Wideband rms Noise

$\pm 2.5V$	100:1	125	115	130	

Short Circuit Currents

Short circuits to ground, positive or negative power supply are allowed as long as the power supplies do not exceed $\pm 5V$ and the ambient temperature stays below $85^\circ C$. Above $\pm 5V$ and at elevated temperatures, continuous

short circuits to the negative power supply will cause excessive currents to flow. Under these conditions, the device will get damaged if the short circuit current is allowed to exceed 80mA.

DEFINITION OF FILTER FUNCTIONS

Each building block of the LTC1060, together with an external clock and a few resistors, closely approximates 2nd order filter functions. These are tabulated below in the frequency domain.

Q = Quality factor of the complex pole pair. It is the ratio of f_0 to the $-3dB$ bandwidth of the 2nd order bandpass function. The Q is always measured at the filter BP output.

1. **Bandpass function:** available at the bandpass output pins (2, 19), Figure 1.

$$G(s) = H_{BP} \frac{s\omega_0/Q}{s^2 + (s\omega_0/Q) + \omega_0^2}$$

H_{BP} = Gain at $\omega = \omega_0$

$f_0 = \omega_0/2\pi$; f_0 is the center frequency of the complex pole pair. At this frequency, the phase shift between input and output is -180° .

2. **Lowpass function:** available at the LP output pins (1, 20), Figure 2.

$$G(s) = H_{OLP} \frac{\omega_0^2}{s^2 + s(\omega_0/Q) + \omega_0^2}$$

H_{OLP} = DC gain of the LP output.

DEFINITION OF FILTER FUNCTIONS

3. **Highpass function:** available only in mode 3 at the output pins (3, 18), Figure 3.

$$G(s) = H_{OHP} \frac{s^2}{s^2 + s(\omega_0/Q) + \omega_0^2}$$

H_{OHP} = gain of the HP output for $f \rightarrow \frac{f_{CLK}}{2}$

4. **Notch function:** available at pins 3 (18) for several modes of operation.

$$G(s) = (H_{ON2}) \frac{(s^2 + \omega_n^2)}{s^2 + s(\omega_0/Q) + \omega_0^2}$$

H_{ON2} = gain of the notch output for $f \rightarrow \frac{f_{CLK}}{2}$

H_{ON1} = gain of the notch output for $f \rightarrow 0$

$f_n = \omega_n/2\pi$; f_n is the frequency of the notch occurrence.

5. **Allpass function:** available at pins 3(18) for mode 4, 4a.

$$G(s) = H_{OAP} \frac{[s^2 - s(\omega_0/Q) + \omega_0^2]}{s^2 + s(\omega_0/Q) + \omega_0^2}$$

H_{OAP} = gain of the allpass output for $0 < f < \frac{f_{CLK}}{2}$

For allpass functions, the center frequency and the Q of the numerator complex zero pair is the same as the denominator. Under these conditions, the magnitude response is a straight line. In mode 5, the center frequency f_z of the numerator complex zero pair, is different than f_0 . For high numerator Q's, the magnitude response will have a notch at f_z .

$$Q = \frac{f_0}{f_H - f_L}; f_0 = \sqrt{f_L f_H}$$

$$f_L = f_0 \left(\frac{-1}{2Q} + \sqrt{\left(\frac{1}{2Q}\right)^2 + 1} \right)$$

$$f_H = f_0 \left(\frac{1}{2Q} + \sqrt{\left(\frac{1}{2Q}\right)^2 + 1} \right)$$

Figure 1

$$f_c = f_0 \times \sqrt{\left(1 - \frac{1}{2Q^2}\right) + \sqrt{\left(1 - \frac{1}{2Q^2}\right)^2 + 1}}$$

$$f_p = f_0 \sqrt{1 - \frac{1}{2Q^2}}$$

$$H_{OHP} = H_{OLP} \times \frac{1}{Q \sqrt{1 - \frac{1}{4Q^2}}}$$

Figure 2

$$f_c = f_0 \times \left[\sqrt{\left(1 - \frac{1}{2Q^2}\right) + \sqrt{\left(1 - \frac{1}{2Q^2}\right)^2 + 1}} \right]^{-1}$$

$$f_p = f_0 \times \left[\sqrt{1 - \frac{1}{2Q^2}} \right]^{-1}$$

$$H_{OHP} = H_{OHP} \times \frac{1}{Q \sqrt{1 - \frac{1}{4Q^2}}}$$

MODES OF OPERATION

Figure 17. Mode 6b: 1st Order Filter Providing Lowpass

Figure 18. Mode 7: 1st Order Filter Providing Allpass, Lowpass

COMMENTS ON THE MODES OF OPERATION

There are basically three modes of operation: mode 1, mode 2, mode 3. In the mode 1, Figure 4, the input amplifier is outside the resonant loop. Because of this, mode 1 and its derivatives (mode 1a, 1b, 1c) are faster than modes 2 and 3. In mode 1, for instance, the Q errors are becoming noticeable above 1MHz clock frequency.

Mode 1a, (Figure 5), represents the most simple hook-up of the LTC1060. Mode 1a is useful when voltage gain at the bandpass output is required. The bandpass voltage gain, however, is equal to the value of Q; if this is acceptable, a second order, clock tunable, BP resonator can be achieved with only 2 resistors. The filter center frequency directly depends on the external clock frequency. For high order filters, mode 1a is not practical since it may require several clock frequencies to tune the overall filter response.

Mode 1, Figure 4, provides a clock tunable notch; the depth is shown in graph 14. Mode 1 is a practical configuration for second order clock tunable bandpass/notch filters. In mode 1, a bandpass output with a very high Q, together with unity gain, can be obtained without creating problems with the dynamics of the remaining notch and lowpass outputs.

Modes 1b and 1c, Figures 6,7 are similar. They both produce a notch with a frequency which is always equal to the filter building block center frequency. The notch and the center frequency, however, can be adjusted with an external resistor ratio.

The practical clock to center frequency ratio range is:

$$\frac{500}{1} \geq \frac{f_{CLK}}{f_0} \geq \frac{100}{1} \left(\text{or } \frac{50}{1} \right); \text{ mode 1b}$$

$$\frac{100}{1} \text{ or } \frac{50}{1} \geq \frac{f_{CLK}}{f_0} \geq \frac{100}{\sqrt{2}} \text{ or } \frac{50}{\sqrt{2}}; \text{ mode 1c}$$

The input impedance of the S1 pin is clock dependent, and in general R5 should not be larger than 5k. Mode 1b can be used to increase the clock to center frequency ratio beyond 100:1. For this mode, a practical limit for the (f_{CLK}/f_0) ratio is 500:1. Beyond this, the filter will exhibit large output offsets. Mode 1c is the fastest mode of operation: In the 50:1 mode and with $(R_5 = 0, R_6 = \infty)$ the clock to center frequency ratio becomes $(50/\sqrt{2})$ and center frequencies beyond 20kHz can easily be achieved as shown in graph 25. Figure 19, illustrates how to cascade the two sections of the LTC1060 connected in mode 1c to obtain a sharp fourth order, 1dB ripple, BP Chebyshev filter. Note that the center frequency to the BW ratio for this fourth order bandpass filter is 20/1. By varying the clock frequency to sweep the filter, the center frequency of the overall filter will increase proportionally and, so will the BW to maintain the 20:1 ratio constant. All the modes of operation yield constant Q's; with any filter realization the BW's will vary when the filter is swept. This is shown in Figure 19, where the BP filter is swept from 1kHz to 20kHz center frequency.

COMMENTS ON THE MODES OF OPERATION

Modes 2, 2a, and 2b have a notch output which frequency, f_n , can be tuned independently from the center frequency, f_o . For all cases, however, $f_n < f_o$. These modes are useful when cascading second order functions to create an over-

all elliptic highpass, bandpass or notch response. The input amplifier and its feedback resistors (R_2/R_4) are now part of the resonant loop. Because of this, mode 2 and its derivatives are slower than mode 1's.

Figure 19. Cascading the 2 sections of the LTC1060 connected in mode 1c to obtain a clock tunable 4th order 1dB ripple bandpass Chebyshev filter with $(\text{center frequency}) / (\text{Ripple Bw}) = 20/1$.

In mode 3, Figure 11, a single resistor ratio (R_2/R_4) can tune the center frequency below or above the $f_{CLK}/100$ (or $f_{CLK}/50$) ratio. Mode 3 is a state variable configuration since it provides a highpass, bandpass, lowpass output through progressive integration; notches are obtained by summing the highpass and lowpass outputs (mode 3a, Figure 12). The notch frequency can be tuned below or above the center frequency through the resistor ratio (R_H/R_L). Because of this, modes 3 and 3a are the most versatile and useful modes for cascading second order sections to obtain high order elliptic filters. Figure 20, shows the 2 sections of an LTC1060 connected in mode 3a to obtain a clock tunable 4th order sharp elliptic bandpass filter. The first notch is created by summing directly the HP and LP outputs of the first section into the inverting input of the second section op amp. The individual Q's are 29.6 and the filter maintains its shape and performance up to 20kHz center frequency, Figure 21. For this circuit an external op amp is required to obtain the 2nd notch. The dynamics of

Figure 24 are excellent because the amplitude response at each output pin does not exceed 0dB. The gain in the passband depends on the ratio of $(R_g/R_{h2}) \times (R_{22}/R_{h1}) \times (R_{21}/R_{11})$. Any gain value can be obtained by acting on the (R_g/R_{h2}) ratio of the external op amp, meanwhile the remaining ratios are adjusted for optimum dynamics of the LTC1060 output nodes. The external op amp of Figure 20 is not always required. In Figure 22, one section of the LTC1060 in mode 3a is cascaded with the other section in mode 2b to obtain a 4th order, 1dB ripple, elliptic bandreject filter. This configuration is interesting because a 4th order function with two different notches is realized without requiring an external op amp. The clock to center frequency ratio is adjusted to 200:1; this is done in order to better approximate a linear R,C notch filter. The amplitude response of the filter is shown in Figure 23 with up to 1MHz clock frequency. The 0dB bandwidth to the stop bandwidth ratio is 8/1. When the filter is centered at 1kHz, it should theoretically have a 44dB rejection with a 50Hz

COMMENTS ON THE MODES OF OPERATION

top bandwidth. For a more narrow filter than the above, the unused BP output of the mode 2b section, Figure 22, has a gain exceeding unity which limits the dynamic range of the overall filter. For very selective bandpass/band-

ject filters, the mode 3a approach as in Figure 12, yields better dynamic range since the external op amp helps to optimize the dynamics of the output nodes of the LTC1060.

RESISTOR VALUES

LTC1060 OFFSETS

Switched capacitor integrators generally exhibit higher input offsets than discrete R,C integrators.

These offsets are mainly due to the charge injection of the CMOS switches into the integrating capacitors and they are temperature independent. The internal op amp offsets also add to the overall offset budget and they are typically a couple of millivolts.

Because of this, the DC output offsets of switched capacitor filters are usually higher than the offsets of discrete active filters.

Figure 24 shows half of an LTC1060 filter building block with its equivalent input offsets V_{OS1} , V_{OS2} , V_{OS3} . All three are 100% tested for both sides of the LTC1060. V_{OS2} is generally the larger offset. When the $S_{A/B}$, pin 6, of the LTC 1060 is shorted to the negative supply (i.e., mode 3), the value of the V_{OS2} decreases. Additionally, with $S_{A/B}$ low, a 20%-30% noise reduction is observed. Mode 1 can still be achieved, if desired, by shorting the S1 pin to the lowpass output, Figure 25.

LTC1060 OFFSETS

Figure 24. Equivalent Input Offsets of 1/2 LTC1060 Filter Building Block

Figure 25. Mode 1(LN): Same Operation as Mode 1 but Lower V_{OS2} Offset and Lower Noise

Output Offsets

The DC offset at the filter bandpass output is always equal to V_{OS3} . The DC offsets at the remaining two outputs (Notch and LP) depend on the mode of operation and external resistor ratios. Table 5 illustrates this.

It is important to know the value of the DC output offsets,

especially when the filter handles input signals with large dynamic range. As a rule of thumb, the output DC offsets increase when:

1. The Q's decrease
2. The ratio (f_{CLK}/f_0) increases beyond 100:1. This is done by decreasing either the $(R2/R4)$ or the $R6/(R5 + R6)$ resistor ratios.

Table 5

Mode	V_{OSN} Pin 3 (18)	V_{OSBP} Pin 2 (19)	V_{OSLP} Pin 1 (20)

5th Order Low Pass Filter

FEATURES

- Lowpass Filter with No DC Error
- Low Passband Noise
- Operates DC to 20kHz
- Operates on a Single 5V Supply or Up to $\pm 8V$
- 5th Order Filter
- Maximally Flat Response
- Internal or External Clock
- Cascadable for Faster Rolloff
- Buffer Available
- 8 Pin DIP Package

APPLICATIONS

- 60Hz Lowpass Filters
- Anti-Aliasing Filter
- Low Level Filtering
- Rolling Off AC Signals from High DC Voltages
- Digital Voltmeters
- Scales
- Strain Gauges

DESCRIPTION

The LTC1062 is a 5th order all pole maximally flat lowpass filter with no DC error. Its unusual architecture puts the filter outside the DC path so DC offset and low frequency noise problems are eliminated. This makes the LTC1062 very useful for lowpass filters where DC accuracy is important.

The filter input and output are simultaneously taken across an external resistor. The LTC1062 is coupled to the signal through an external capacitor. This R,C reacts with the internal switched capacitor network to form a 5th order rolloff at the output.

The filter cutoff frequency is set by an internal clock which can be externally driven. The clock to cutoff frequency ratio is typically 100:1, allowing the clock ripple to be easily removed.

Two LTC1062s can be cascaded to form a 10th order quasi max flat lowpass filter. The device can be operated with single or dual supplies ranging from $\pm 2.5V$ to $\pm 9V$.

The LTC1062 is manufactured using Linear Technology's enhanced LTCMOSTTM silicon gate process.

LTCMOSTTM is a trademark of Linear Technology Corp.

TYPICAL APPLICATION

10Hz 5th Order Butterworth Lowpass Filter

NOTE: TO ADJUST OSCILLATOR FREQUENCY, USE A 6800pF CAPACITOR IN SERIES WITH A 50K POT FROM PIN 5 TO GROUND.

Max Clock Frequency			4		MHz
Pin 5 Source or Sink Current			40	80	μA

The ● denotes the specifications which apply over the full operating temperature range.

Note 1: f_C is the frequency where the gain is –3dB with respect to the input signal.

Note 2: The LTC1062M operates from $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$, the LTC1062C operates from $-40^\circ\text{C} \leq T_A \leq 85^\circ\text{C}$.

Note 3: The external or driven clock frequency is divided by either 1, 2, or 4 depending upon the voltage at pin 4. When pin 4 = V^+ , ratio = 1; when pin 4 = GND, ratio = 2; when pin 4 = V^- , ratio = 4.

BLOCK DIAGRAM

BY CONNECTING PIN 4 TO V^+ , AGND, OR V^- , THE OUTPUT FREQUENCY OF THE INTERNAL CLOCK GENERATOR IS THE OSCILLATOR FREQUENCY DIVIDED BY 1.24. THE (f_{CLK}/f_C) RATIO OF 100:1 IS WITH RESPECT TO THE INTERNAL CLOCK GENERATOR OUTPUT FREQUENCY. PIN 5 CAN BE DRIVEN WITH AN EXTERNAL CMOS LEVEL CLOCK. THE LTC1062 CAN ALSO BE SELF-CLOCKED BY CONNECTING AN EXTERNAL CAPACITOR (C_{OSC}) TO GROUND (OR TO V^- IF C_{OSC} IS POLARIZED). UNDER THIS CONDITION AND WITH $\pm 5V$ SUPPLIES, THE INTERNAL OSCILLATOR FREQUENCY IS:

$$f_{OSC} \approx 140\text{kHz} [33\text{pF}/(33\text{pF} + C_{OSC})].$$

For Adjusting Oscillator Frequency, Insert a 50K Pot in Series with C_{OSC} . Use Two Times Calculated C_{OSC} .

APPLICATIONS INFORMATION

Filter Input Voltage Range

Every node of the LTC1062 typically swings within 1V of either voltage supply, positive or negative. With the appropriate external (R,C) values, the amplitude response of all the internal or external nodes does not exceed a gain of 0 dB with the exception of pin 1. The amplitude response of the feedback node (pin 1) is shown in Figure 2. For an input frequency around $0.8 \times f_C$, the gain is 1.7 V/V and, with

$\pm 5\text{V}$ supplies, the peak-to-peak input voltage should not exceed 4.7V. If the input voltage goes beyond this value, clipping and distortion of the output waveform occur, but the filter will not get damaged nor will it oscillate. Also, the absolute maximum input voltage should not exceed the power supplies.

APPLICATIONS INFORMATION

Figure 2. Amplitude Response of Pin 1

Internal Buffer

The internal buffer out (pin 8) and pin 1 are part of the signal AC path. Excessive capacitive loading will cause phase errors in the passband, especially around the cutoff frequency. The internal buffer gain at DC is typically 0.006dB. The internal buffer output can be used as a filter output, however it has a few millivolts of DC offset. The temperature coefficient of the internal buffer is typically $\mu\text{V}/^\circ\text{C}$.

Filter Attenuation

The LTC1062 rolloff is typically 30dB/octave. When the clock, and the cutoff frequencies increase, the filter's maximum attenuation decreases. This is shown in the typical Performance Characteristics. The decrease of the maximum attenuation, is due to the roll off at higher frequencies of the loop gains of the various internal feedback paths and not to the increase of the noise floor. For instance, for a 100kHz clock and 1kHz cutoff frequency, the maximum attenuation is about 64dB. A 4kHz, 1Vrms input signal will be predictably attenuated by 60dB at the output. A 6kHz, 1Vrms input signal will be attenuated by 4dB and not by 77dB as an ideal 5th order maximum flat filter would have dictated. The LTC1062 output at 6kHz will be about 630 μV rms. The measured rms noise from DC to 7kHz was 100 μV rms which is 16dB below the filter output.

COSC, Pin 5

The C_{OSC}, pin 5, can be used with an external capacitor, C_{OSC}, connected from pin 5 to ground. If C_{OSC} is polarized it should be connected from pin 5 to the negative supply, pin 3. C_{OSC} lowers the internal oscillator frequency. If pin 5 is floating, an internal 33pF capacitor plus the external interpin capacitance set the oscillator frequency around 140kHz with $\pm 5\text{V}$ supply. An external C_{OSC} will bring the oscillator frequency down by the ratio $(33\text{pF})/(33\text{pF} + \text{C}_{\text{OSC}})$. The typical performance characteristics curves provide the necessary information to get the internal oscillator frequency for various power supply ranges. Pin 5 can also be driven with an external CMOS clock to override the internal oscillator. Although standard 7400 series CMOS gates do not guarantee CMOS levels with the current source and sink requirements of pin 5, they will, in reality, drive the C_{OSC} pin. CMOS gates conforming to standard B series output drive have the appropriate voltage levels and more than enough output current to simultaneously drive several LTC1062 C_{OSC} pins. The typical trip levels of the internal Schmitt trigger which input is pin 5, are given below.

POWER SUPPLY		TRIP LEVELS	
V ⁺ = +5V	V ⁻ = 0V	V _H = 3.4V	V _L = 1.35V
V ⁺ = +10V	V ⁻ = 0V	V _H = 6.5V	V _L = 2.8V
V ⁺ = +15V	V ⁻ = 0V	V _H = 9.5V	V _L = 4.1V

APPLICATIONS INFORMATION

Divide By 1, 2, 4 (Pin 4)

By connecting pin 4 to V^+ , to mid supplies or to V^- , the clock frequency driving the internal switched capacitor network is the oscillator frequency divided by 1, 2, 4, respectively. Note that the f_{CLK}/f_C ratio of 100:1 is with respect to the internal clock generator output frequency. The internal divider is useful for applications where octave tuning is required. The ± 2 threshold is typically $\pm 1V$ from the mid supply voltage.

Transient Response

Figure 3 shows the LTC1062 response to a 1V input step. The settling time approximates that of an ideal 5th order maximally flat filter.

Figure 3. LTC1062 Transient Response

Table 1

NOISE BW	rms NOISE $V_S = \pm 5V$
DC – $0.1 \times f_C$	$2\mu V$
DC – $0.25 \times f_C$	$8\mu V$
DC – $0.5 \times f_C$	$20\mu V$
DC – $1 \times f_C$	$62\mu V$
DC – $2 \times f_C$	$100\mu V$

Filter Noise

The filter wideband rms noise is typically $100\mu V_{rms}$ for $\pm 5V$ supply and it is nearly independent from the value of the cutoff frequency. For single 5V supply the rms noise is $80\mu V_{rms}$. Sixty-two percent of the wideband noise is in the passband, that is from DC to f_C . The noise spectral density, unlike conventional active filters, is nearly zero for frequencies below $0.1 \times f_C$. This is shown in the typical performance characteristics section. Table 1 shows the LTC1062 rms noise for different noise bandwidths.

Regulating Pulse Width Modulator

FEATURES

- *Guaranteed* $\pm 2\%$ Reference Tolerance
- *Guaranteed* $\pm 6\%$ Oscillator Tolerance
- *Guaranteed* 10mV/1000 Hrs Long Term Stability
- Interchangeable with all SG1524 or LM1524 Devices
- Operates Above 100kHz

APPLICATIONS

- Switching Power Supplies
- Motor Speed Control
- Off-Line Power Converters

DESCRIPTION

The LT1524 PWM switching regulator control circuit contains all the essential circuitry to implement single-ended or push-pull switching regulators. Included on the circuit are oscillator, voltage reference, a pulse width modulator, error amplifier, overload protection circuitry and output drivers.

Although pin-for-pin and functionally compatible with industry standard 1524 and 3524 devices, Linear Technology has incorporated several improvements in the design of the LT1524. A subsurface zener reference has been used to provide excellent stability with time and the reference is trimmed at the wafer level to provide an initial accuracy of 2%. Additionally, the oscillator is trimmed to provide a maximum tolerance of 6%.

Linear Technology Corporation's advanced processing, design and passivation techniques make the LT1524 and LT3524 a superior and more reliable choice over previous devices.

The ● denotes specifications that apply over the full operating temperature range.

The shaded electrical specifications indicate those parameters which have been improved or guaranteed test limits provided for the first time.

Note 1: For operating at elevated temperatures, the device in the J package must be derated at 100°C/W to a maximum junction temperature of 150°C, while the device in the N package is derated at 150°C/W to a maximum junction temperature of 115°C.

Note 2: These specifications apply for $V_{IN} = 20V$, $f = 20kHz$, $T_A = 25^\circ C$ unless otherwise noted.

Note 3: Although many manufacturers specify a maximum specification of 2%, Linear Technology's experience is that this specification is not being presently met by other manufacturers. Linear Technology's basic design, although improved, is essentially identical to other manufacturers' devices. Linear Technology is, however, unwilling to place a maximum specification on its data sheet which cannot be met or guaranteed.

Note 4: Standby current does not include the oscillator charging current, error and current limit dividers, and the outputs are open circuit.

TEST CIRCUIT

TYPICAL PERFORMANCE CHARACTERISTICS

APPLICATIONS INFORMATION

FUNCTIONAL DESCRIPTION AND PIN FUNCTIONS

Voltage Regulator

The internal 5V regulator (input pin 15, output pin 16) supplies a regulated 5V to all internal circuitry, as well as up to 50mA for external circuitry. For operation below 8V input, pins 15 and 16 may be tied together and 5V to 6V externally applied.

Oscillator

The internal oscillator circuitry sets the frequency of operation for the switching regulator. The oscillator waveform is a ramp from about 1V to 3.5V (pin 7). Frequency is set by a timing resistor from pin 6 to ground and a capacitor from pin 7 to ground. The oscillator period is approximately RC for the recommended range of 1.8k to 100k for R and 0.001 μ F to 0.1 μ F for C .

The fall time of the ramp sets the blanking or dead time where both outputs are off in push-pull regulators. This is controlled by the value of the capacitor alone.

Output Transistors

The two output transistors have both the emitters (pins 11 and 14) and the collectors available (pins 12 and 13). Internal current limiting for both of these transistors is about 100mA. The two transistors are driven 180° out of phase by the flip-flop. For single-ended operation they should be connected in parallel.

Error Amplifier

The differential input (pins 1 and 2) single-ended output (pin 9) transconductance amplifier provides about 80dB of gain, as well as providing a point for loop frequency compensation or electronic shutdown.

DC gain of the loop can be controlled by resistive loading, while AC compensation is usually accomplished with a series R-C connected from pin 9 to ground. The output impedance at pin 9 is about 5M Ω and current is about 200 μ A, so external op-amps or voltage sources can easily drive the comparator input. Normally, the 5V reference is divided down to generate a voltage within the common-mode range of the error amplifier.

Synchronous Operation

When an external clock is desired, a clock pulse of approximately 3V can be applied directly to the oscillator output, pin 3. The impedance to ground at this point is approximately 2k Ω . In this configuration, R_T C_T must be selected for a clock period slightly greater than that of the external clock.

If two or more LT1524 regulators are to be operated synchronously, all oscillator output terminals should be tied together. The oscillator programmed for the minimum clock period will be the master from which all the other LT1524s operate. In this application, the C_T R_T values of the slaved regulators must be set for a period approximately 10% longer than that of the master regulator. In addition, C_T (master) = 2 C_T (slave) to ensure that the master output pulse, which occurs first, has a wider pulse width and will subsequently reset the slave regulators.

Shutdown

A logic high at pin 10 will shut down the regulator and cause both output transistors to turn off.

Current Limit

Current limiting is activated when the voltage between pins 4 and 5 exceeds 200mV. The output of the current limit amplifier internally sums with the error amplifier to shorten the output pulse width. The gain of the current limit circuitry is relatively low, so current control in limit is typically about 5%. Two areas of caution should be observed with current limiting. First, the response time of the current limit is set by the loop roll-off on pin 9. Fast current limiting requires external circuitry. Second, the common-mode range of the current limit amplifier is limited. Even fast spikes outside this range can disrupt operation.

FEATURES

- Undervoltage Lockout with Hysteresis
- *Guaranteed* 1% 5.1V Reference
- *Guaranteed* 10mV / 1000 Hr Long Term Stability
- Latching PWM
- 8V to 35V Operation
- 100Hz to 400kHz Oscillator
- 400mA Source and Sink Current

APPLICATIONS

- Switching Power Supplies
- Motor Speed Control
- Power Converters

DESCRIPTION

The LT1525A and LT1527A are improved general purpose switching regulator control circuits. Included on the chip are a trimmed 1% voltage subsurface zener reference, oscillator, comparator and high current class B totem pole output drivers. Included in the design of the LT1525A are easy synchronization to an external clock, soft-start and adjustable deadtime control. A shutdown pin allows instantaneous shutdown.

The LT1525A and LT1527A differ only in their output logic phasing. The LT1525A has a low output during the "off" state, while the LT1527A has a high output during the "off" state. Both devices have undervoltage lockout with about 0.5V hysteresis, giving reliable operation even with slowly varying supplies.

The combination of improved features and advanced processing for high reliability make Linear Technology's switching regulators a supreme choice.

APPLICATIONS INFORMATION

Shutdown Options

1. An external open collector comparator or transistor can be used to pull down the compensation pin (9). This will set the PWM latch and turn off both outputs. Pulse-by-pulse protection can be accomplished if the shutdown signal is momentary, since the PWM latch will be reset with each clock pulse.
2. Shutdown can also be accomplished by pulling down on the soft-start pin (8). When using this approach, shutdown will not affect the amplifier compensation network; however, if a soft-start capacitor is used, it must be discharged, possibly slowing shutdown response.

APPLICATIONS INFORMATION

- Applying a positive-going signal to the shutdown pin (10) will provide the most rapid shutdown of the outputs if a soft-start capacitor is not used at pin 8. An external soft-start capacitor at pin 8 will slow shutdown response due to the discharge time of the soft-start capacitor. Discharge current is approximately twice the charging current.
- The shutdown terminal can be used to set the PWM latch on a pulse-by-pulse basis if there is no external capacitance on pin 8. Soft-start characteristics may still be achieved by applying an external capacitor, blocking diode and charging resistor to the compensation pin (9).

TYPICAL APPLICATIONS

DESCRIPTION

The LT1526 is an improved general purpose switching regulator control circuit. Included on the chip are a 1% voltage reference, oscillator, error amplifier, pulse width modulator and low impedance output drivers. Also included are protective features such as a current limit comparator, undervoltage lockout, soft-start circuitry, and adjustable deadtime. This versatile device can be used to implement single-ended or push-pull switching regulators of either polarity, both transformerless and transformer-coupled.

Although pin-for-pin and functionally compatible with industry standard 1526 and 3526 devices, Linear Technology has incorporated several improvements in the design of the LT1526. A subsurface zener has been used to provide excellent reference voltage stability and the reference offers improved line regulation and load regulation. The current limit comparator sense voltage initial accuracy and temperature stability have been greatly improved.

The combination of improved features and advanced linear processing for high reliability make Linear Technology's switching regulators a superior choice.

APPLICATIONS INFORMATION

FUNCTIONAL DESCRIPTION AND PIN FUNCTION

Voltage Reference

The reference regulator (pin 18) supplies a regulated 5.0V to all internal circuitry, as well as up to 20mA for external circuitry. It is fully active at supply voltages (pin 17) of 8V and greater.

The LT1526 can operate from a 5V supply by connecting $+V_{IN}$ to V_{REF} (pin 18 to pin 17) and maintaining the supply between 4.8V and 5.2V.

Undervoltage Lockout

The undervoltage lockout circuitry protects both the switching regulator and the power devices it controls from inadequate supply voltage, which can result in unstable control circuitry. If $+V_{IN}$ is too low, the circuit turns off the output drivers, holds $\overline{RESET}$ (pin 5) low and the soft-start capacitor in a discharged state.

Soft-Start

The soft-start circuitry protects the power devices from high surge currents during power supply turn-on by limiting the available PWM duty cycle.

When $+V_{IN}$ reaches a sufficient voltage to allow $\overline{RESET}$ to go high, a 100 μ A current source charges the external C_S capacitor (pin 4) linearly to 5V. The ERROR AMPLIFIER output is clamped to 600mV above the C_S voltage, and the available duty cycle of the PWM increases linearly. Maximum duty cycle is available when the C_S voltage reaches about 3V.

Digital Control Ports

The three digital control ports are bidirectional. Each port can drive TTL and 5V CMOS logic directly. They can also be driven by open-collector TTL, open-drain CMOS, and open-collector voltage comparators.

Driving $\overline{SYNC}$ (pin 12) low causes a discharge cycle in the oscillator. Driving $\overline{SHUTDOWN}$ (pin 8) low causes the outputs to turn off. Driving $\overline{RESET}$ (pin 5) low causes the outputs to turn off and discharges the C_S capacitor.

Oscillator

The internal oscillator circuitry sets the frequency of operation for the switching regulator. Frequency is set by R_T (pin 9), C_T (pin 10), and R_D (pin 11). With $R_D = 0\Omega$, the values for R_T and C_T may be chosen from the oscillator period graph. If the desired deadtime is increased, the value of R_T may need to be decreased to maintain the desired frequency.

The frequency at either output is half that of the oscillator, and the frequency at $+V_C$ (pin 14) is equal to the oscillator.

Synchronous Operation

Two or more switching regulators may be synchronized by setting the master to the desired frequency and sharing the oscillator signals with the slave units. Slave C_T pins are tied to the master C_T pin, and slave $\overline{SYNC}$ pins are tied to the master $\overline{SYNC}$ pin. Slave R_T and R_D pins are left open.

External logic synchronization can be used by setting the oscillator period to be 10% longer than the external clock period, and connecting the external clock to the $\overline{SYNC}$ pin. A periodic low of about 0.5 μ s wide will lock the oscillator to the external frequency.

Error Amplifier

The differential input (pins 1 and 2), single-ended output (pin 3) transconductance amplifier provides about 70dB of gain. The output has an impedance of 2M Ω , and since all voltage gain occurs at the output, the gain characteristics can be controlled with shunt reactance to ground.

Output Drivers

The totem-pole output drivers can source and sink 100mA continuously and 200mA peak. The outputs are driven 180° out of phase by the flip-flop. Loads can be driven either from the outputs or the $+V_C$ pin. Since large transient currents occur within the output stages during switching, a resistor is recommended in series with $+V_C$ (pin 14) to limit the peak current. The resistor value should be $+V_C/200\text{mA}$.

APPLICATIONS INFORMATION

Current Limit

The current limit comparator turns off the outputs when the input voltage (pin 7 to pin 6) exceeds 100mV. Hystere-

sis is built into the trip point, of about 10mV, to prevent oscillations.

TYPICAL APPLICATIONS

Single Ended Supply

FOR SINGLE ENDED SUPPLIES, THE DRIVER OUTPUTS ARE GROUNDED. THE +V_C TERMINAL IS SWITCHED TO GROUND BY THE TOTEM POLE SOURCE TRANSISTORS ON EVERY OSCILLATOR CYCLE.

Bipolar Push-Pull Supply

IN CONVENTIONAL BIPOLAR PUSH-PULL DESIGNS, FORWARD BASE DRIVE IS CONTROLLED BY R1-R3. RAPID TURN-OFF TIMES FOR THE POWER DEVICES ARE ACHIEVED WITH SPEED-UP CAPACITORS C1 AND C2.

Driving Transformers Directly

LOW POWER TRANSFORMERS CAN BE DRIVEN DIRECTLY BY THE LT1526. AUTOMATIC RESET OCCURS DURING DEAD-TIME, WHEN BOTH ENDS OF THE PRIMARY WINDING ARE SWITCHED TO GROUND.

Power FETs Push-Pull Supply

- Power Converters

Current Mode PWM Controller DESCRIPTION

The UC1846 family of control ICs contains all necessary circuitry to implement fixed frequency, fixed output voltage, current mode control schemes. Current mode control loops are easy to design and compensate, and provide superior transient line regulation, inherent pulse-by-pulse current limiting, and automatic symmetry correction for push-pull converters. In addition, the UC1846 has built-in undervoltage lockout with hysteresis to prevent oscillations near the threshold, soft-start capability, and can be shut down instantaneously by an external logic level. Internal logic prevents double-pulsing and output overlap.

The oscillator circuitry of the UC1846 allows the user to adjust output deadtime as well as frequency and also provides a bidirectional sync pin to allow paralleling power modules.

Both the internal error amplifier and current sense amplifiers operate over a wide common-mode range to allow design flexibility. The dual outputs provide active pull up/pull down, ideal for driving bipolar or FET switches. The internal reference regulator provides excellent stability for changes in line, load, and temperature. The UC1846 outputs are low in the off state while the UC1847 outputs are high in the off state.

The ● denotes the specifications that apply over the full operating temperature range.

Note 1: All voltages are with respect to Ground, pin 12. Currents are positive into, negative out of the specified terminal.

Note 2: Derate at 10mW/°C for T_A above 50°C.

Note 3: Derate at 16mW/°C for T_C above 25°C.

Note 4: Unless otherwise stated $V_{IN} = 15V$, $R_T = 10k$, $C_T = 4.7nF$.

Note 5: These parameters, although guaranteed over the recommended operating conditions are not 100% tested in production.

Note 6: Parameter measured at trip point of latch with $V_{Pin5} = V_{REF}$, $V_{Pin6} = 0V$.

Note 7: Amplifier gain defined as

$$G = \frac{\Delta V_{Pin7}}{\Delta V_{Pin4}}; \Delta V_{Pin4} = 0V \text{ to } 1.0V$$

Note 8: Current into pin 1 guaranteed to latch circuit in shutdown state.

Note 9: Current into pin 1 guaranteed not to latch circuit in shutdown state.

Note 10: Applies to UC1846/3846 only due to polarity of outputs.

Note 11: Standby current does not include oscillator charging current, error and current limit dividers, and the outputs are open circuit.

APPLICATIONS INFORMATION

Current Mode Control

Current mode controllers directly control peak inductor current with the error signal rather than controlling the duty cycle of the PWM as conventional controllers do. There are several inherent advantages in this type of control.

Current mode controllers are easier to frequency compensate. Peak inductor current is forced to follow the error signal and can change only if the error signal changes. This forces the inductor to act like a constant current source at mid frequencies and the order of the system can be reduced by one, eliminating 90° of phase shift.

Peak current on a pulse-by-pulse basis can be limited by simply limiting the positive swing of the error amplifier.

Transient line regulation is greatly improved. A change in the line voltage causes a change in the slope of the inductor current. This means that the time it takes for the inductor current to reach the peak control value automatically changes, and requires very little change in the output of the error amp. Since transient response is limited by the integrator response of the error amplifier, excellent line transient response is obtained if the error amplifier output does not have to change.

APPLICATIONS INFORMATION

With current mode control, some amount of slope compensation is required to prevent oscillations for duty cycles greater than 50%. Slope compensation can also be used to decrease noise sensitivity for low values of inductor current ripple, and to prevent subharmonic oscillations in the inductor current.

Shutdown/Soft Start

A logic high at pin 16 will initiate a shutdown cycle. During a shutdown cycle, both outputs are held off and pins 1 and 7 are pulled low. If pin 1 current ($I_{Pin 1} = V_{REF}/R_1$) is less than the latch threshold current, typically 1.5mA (see Electrical Characteristics), the device will restart at the end of the shutdown pulse. If pin 1 current is greater than the latch threshold current, the device will latch off until power is recycled.

Soft start is accomplished by the addition of a capacitor from pin 1 to ground. This forces the peak value of the switch current to come up slowly. Pin 16 can be left floating if the shutdown function is not used.

Undervoltage Lockout

The purpose of the undervoltage lockout is to prevent the device from switching until the internal circuitry is operating properly. Built-in hysteresis prevents the circuit from oscillating at the threshold point. Pin 1 (current limit adjust) and pin 7 (comp) are held low during undervoltage lockout, and outputs are low (UC1846) or high (UC1847).

Output Switches

Oscillator Section

The frequency of the oscillator is set by an external resistor (R_T) from pin 9 to ground, and an external capacitor (C_T) from pin 8 to ground. C_T is charged by a constant current $I_{RT} = V_{Pin 9} / R_T$ ($\approx 3.6V/R_T$), and is discharged by a constant current $8mA - I_{RT}$. Upper and lower trip levels are determined by the internal circuitry, such that the oscillator frequency is approximated by the formula

$$f_T \approx \frac{2.2}{R_T(\Omega)C_T(F)}$$

In addition, output deadtime, which is equal to the capacitor discharge time, is a function of the size of C_T and can be calculated according to the formula:

$$T_d = 145C_T \left(\frac{8mA}{8mA - \frac{3.6V}{R_T}} \right)$$

For large values of R_T (small I_{RT}): $T_d \approx 145C_T$.

Current Limit

Peak switch current on a pulse-by-pulse basis is a function of the voltage level set at pin 1 and the current sense resistor R_s , and can be determined by the formula:

$$I_s = \frac{R_2 V_{REF} - 0.5V}{R_1 + R_2}$$

$$G \bullet R_s$$

$$G = I/A \text{ GAIN} = 2.75 \text{ TYP}$$

APPLICATIONS INFORMATION

Current Sensing

The current sense amplifier is a differential amplifier with a gain of 3 and a common-mode range of 0 to $V_{IN} - 3V$. Maximum differential input signal is 1.2V. Several sensing schemes are possible. Direct resistive sensing is the simplest, but power losses in the resistor may not be acceptable. The use of a current sense transformer will increase efficiency for higher current levels, but will increase circuit complexity. In configurations where switch current is sensed, a small RC may be necessary to keep switch turn on transients from tripping the current sense latch. Without this filter, erratic operation will result especially at lower values of output current. Minimum on-time of the output switch during a short circuit is equal to the delay from the current sense amplifier to the output, typically 200ns. This delay will be longer if a filter for switch transients is added. For best noise immunity, the signal at the current sense amplifier inputs should be as large as possible.

Error Amplifier

The error amplifier of the UC1846 can operate over a common-mode range of 0 to $V_{IN} - 2V$. The output stage consists of an NPN Darlington pull-down and a 0.5mA current source pull-up. See Typical Performance Characteristics for gain and phase characteristics.

Reference Regulator

The reference regulator provides a fixed 5.1V for internal circuitry as well as up to 20mA of output current for external circuitry such as the current limit divider. A small bypass capacitor (0.1–1.0 μ F) from the reference pin (pin 2) to the ground pin (pin 12) is recommended. This capacitor should be located as close as possible to the device.

Slope Compensation

Slope compensation can be accomplished by summing a triangle wave derived from the oscillator waveform, with the inductor current waveform at the current sense amplifier input or the summing node of the error amplifier as shown below. Slope compensation should be greater than 1/2 of the downslope of the inductor current waveform.

Dual Precision Instrumentation Switched-Capacitor Building Block

FEATURES

- Instrumentation Front End with 120dB CMRR
- Precise, Charge-Balanced Switching
- Operates from 3V to 18V
- Internal or External Clock
- Operates up to 5MHz Clock Rate
- Low Power
- Two Independent Sections with One Clock

APPLICATIONS

- Precision Instrumentation Amplifiers
- Ultra Precision Voltage Inverters, Multipliers and Dividers
- V-F and F-V Converters
- Sample and Hold
- Switched-Capacitor Filters

DESCRIPTION

The LTC1043 is a monolithic, charge-balanced, dual switched-capacitor instrumentation building block. A pair of switches alternately connects an external capacitor to an input voltage and then connects the charged capacitor across an output port. The internal switches have a break-before-make action. An internal clock is provided and its frequency can be adjusted with an external capacitor. The LTC1043 can also be driven with an external CMOS clock.

The LTC1043, when used with low clock frequencies, provides ultra precision DC functions without requiring precise external components. Such functions are differential voltage to single-ended conversion, voltage inversion, voltage multiplication and division by 2, 3, 4, 5, etc. The LTC1043 can also be used for precise V-F and F-V circuits without trimming, and it is also a building block for switched-capacitor filters, oscillators and modulators.

The LTC1043 is manufactured using Linear Technology's enhanced LTCMOS™ silicon gate process.

APPLICATIONS INFORMATION

Common-Mode Rejection Ratio (CMRR)

The LTC1043, when used as a differential to single-ended converter (Figure 1) rejects common-mode signals and preserves differential voltages. Unlike other techniques, the LTC1043's CMRR does not degrade with increasing common-mode voltage frequency. During the sampling mode, the impedance of pins 2, 3 (and 11, 12) should be reasonably balanced, otherwise, common-mode signals will appear differentially. The value of the CMRR depends on the value of the sampling and holding capacitors (C_S , C_H) and on the sampling frequency. Since the common-mode voltages are not sampled, the common-mode signal frequency can well exceed the sampling frequency without experiencing aliasing phenomena. The CMRR of Figure 1

Figure 1. Differential to Single-Ended Converter

APPLICATIONS INFORMATION

is measured by shorting pins 7 and 13 and by observing, with a precision DVM, the change of the voltage across C_H with respect to an input CM voltage variation. During the sampling and holding mode, charges are being transferred and minute voltage transients will appear across the holding capacitor. Although the R_{ON} on the switches is low enough to allow fast settling, as the sampling frequency increases, the rate of charge transfer increases and the average voltage measured with a DVM across it will increase proportionally; this causes the CMRR of the sampled data system, as seen by a "continuous" instrument (DVM), to decrease, Figure 2.

Switch Charge Injection

Figure 3 shows one out of the eight switches of the LTC1043, configured as a basic sample and hold circuit. When the switch opens, a "hold step" is observed and its magnitude depends on the value of the input voltage. Figure 4 shows charge injected into the hold capacitor. For instance, a 2pCb of charge injected into a 0.01 μ F capacitor causes a 200 μ V hold step. As shown in Figure 4, there is a predictable and repeatable charge injection cancellation when the input voltage is close to half the supply voltage of the LTC1043. This is a unique feature of this product, containing charge-balanced switches fabricated with a self-aligning gate CMOS process. Any switch of the LTC1043, when powered with symmetrical dual supplies, will sample and hold small signals around ground without any significant error.

Figure 2. CMRR vs Sampling Frequency

Shielding the Sampling Capacitor for Very High CMRR

Internal or external parasitic capacitors from the C^+ pin(s) to ground affect the CMRR of the LTC1043, (Figure 1). The common-mode error due to the internal junction capacitances of the C^+ pin(s) 2 and 11 is cancelled through internal circuitry. The C^+ pin, therefore, should be used as the top plate of the sampling capacitor. The interpin capacitance between pin 2 and dummy pin 1 (11 and 10) appears in parallel with the sampling capacitor so it does not degrade the CMRR. A shield placed underneath the sampling capacitor (Figure 5) and connected to either pin 1 or 3 helps to boost the CMRR in excess of 120dB.

Excessive external parasitic capacitance between the C^- pins and ground indirectly degrades CMRR; this becomes visible especially when the LTC1043 is used with clock frequencies above 2kHz. Because of this, if a shield is used, the parasitic capacitance between the shield and circuit ground should be minimized.

It is recommended that the outer plate of the sampling capacitor be connected to the C^- pin(s).

Input Pins, SCR Sensitivity

An internal 60 Ω resistor is connected in series with the input of the switches (pins 5, 6, 7, 8, 13, 14, 15, 18) and it is included in the R_{ON} specification. When the input voltage exceeds the power supply by a diode drop, current will flow into the input pin(s). The LTC1043 will not

Figure 3

APPLICATIONS INFORMATION

latch until the input current reaches 2mA–3mA. The device will recover from the latch mode when the input drops 3V–4V below the voltage value which caused the latch. For instance, if an external resistor of 200Ω is connected in series with an input pin, the input can be taken 1.3V above the supply without latching the IC. The same applies for the C⁺ and C[−] pins.

Cosc Pin (16), Figure 6

The C_{osc} pin can be used with an external capacitor, C_{osc}, connected from pin 16 to pin 17, to modify the internal oscillator frequency. If pin 16 is floating, the internal 24pF capacitor plus any external interpin capacitance set the oscillator frequency around 190kHz with ±5V supply. The typical performance characteristics curves provide the necessary information to set the oscillator fre-

quency for various power supply ranges. Pin 16 can also be driven with an external clock to override the internal oscillator. Although standard 7400 series CMOS gates do not guarantee CMOS levels with the current source and sink requirements of pin 16, they will in reality drive the C_{osc} pin. CMOS gates conforming to standard B series output drive have the appropriate voltage levels and more than enough output current to simultaneously drive several LTC1043 C_{osc} pins. The typical trip levels of the Schmitt trigger, Figure 6, are given below.

SUPPLY	TRIP LEVELS	
V ⁺ = 5V, V [−] = 0V	V _H = 3.4V	V _L = 1.35V
V ⁺ = 10V, V [−] = 0V	V _H = 6.5V	V _L = 2.8V
V ⁺ = 15V, V [−] = 0V	V _H = 9.5V	V _L = 4.1V

Switched Capacitor Voltage Converter

FEATURES

- Plug-In Compatible with 7660 with These Additional Features:
 - *Guaranteed* Operation to 9V, with No External Diode, Over Full Temperature Range
 - Boost Pin (Pin 1) for Higher Switching Frequency
 - Lower Quiescent Power
 - Efficient Voltage Doubler
- 200 μ A Max. No Load Supply Current at 5V
- 97% Min. Open Circuit Voltage Conversion Efficiency
- 95% Min. Power Conversion Efficiency
- Wide Operating Supply Voltage Range, 1.5V to 9V
- Easy to Use
- Commercial Device *Guaranteed* Over -40°C to 85°C Temperature Range

APPLICATIONS

- Conversion of +5V to $\pm 5\text{V}$ Supplies
- Precise Voltage Division, $V_{\text{OUT}} = V_{\text{IN}} / 2 \pm 20\text{ppm}$
- Voltage Multiplication, $V_{\text{OUT}} = \pm nV_{\text{IN}}$
- Supply Splitter, $V_{\text{OUT}} = \pm V_{\text{S}} / 2$

DESCRIPTION

The LTC1044 is a monolithic CMOS switched capacitor voltage converter which is manufactured using Linear Technology's enhanced LTCMOS™ silicon gate process. The LTC1044 provides several voltage conversion functions: the input voltage can be inverted ($V_{\text{OUT}} = -V_{\text{IN}}$), doubled ($V_{\text{OUT}} = 2V_{\text{IN}}$), divided ($V_{\text{OUT}} = V_{\text{IN}} / 2$) or multiplied ($V_{\text{OUT}} = \pm nV_{\text{IN}}$).

Designed to be pin-for-pin and functionally compatible with the popular 7660, the LTC1044 provides significant features and improvements over earlier 7660 designs. These improvements include: full 1.5V to 9V supply operation over the entire operating temperature range, without the need for external protection diodes; $2\frac{1}{2}$ times lower quiescent current for greater power conversion efficiency; and a "boost" function which is available to raise the internal oscillator frequency to optimize performance in specific applications.

Although the LTC1044 provides significant design and performance advantages over the earlier 7660 device, it still maintains its compatibility with existing 7660 designs.

LTCMOS™ is a trademark of Linear Technology Corp.

Note 1: Absolute Maximum Ratings are those values beyond which the life of the device may be impaired.

Note 2: Connecting any input terminal to voltages greater than V^+ or less than ground may cause destructive latch-up. It is recommended that no inputs from sources operating from external supplies be applied prior to power-up of the LTC1044.

Note 3: The LTC1044 is guaranteed to operate with alkaline, mercury or NiCad 9V batteries, even though the initial battery voltage may be slightly higher than 9.0V.

Note 4: f_{OSC} is tested with $C_{OSC} = 100pF$ to minimize the effects of test fixture capacitance loading. The 1pF frequency is correlated to this 100pF test point, and is intended to simulate the capacitance at pin 7 when the device is plugged into a test socket and no external capacitor is used.

APPLICATIONS INFORMATION

Theory of Operation

To understand the theory of operation of the LTC1044, a review of a basic switched capacitor building block is helpful.

In Figure 2, when the switch is in the left position, capacitor $C1$ will charge to voltage $V1$. The total charge on $C1$ will be $q1 = C1V1$. The switch then moves to the right, discharging $C1$ to voltage $V2$. After this discharge time, the charge on $C1$ is $q2 = C1V2$. Note that charge has been transferred from the source, $V1$, to the output, $V2$. The amount of charge transferred is:

$$\Delta q = q1 - q2 = C1(V1 - V2).$$

If the switch is cycled f times per second, the charge transfer per unit time (i.e., current) is:

$$I = f \times \Delta q = f \times C1(V1 - V2).$$

Figure 2. Switched Capacitor Building Block

APPLICATIONS INFORMATION

Rewriting in terms of voltage and impedance equivalence,

$$I = \frac{V1 - V2}{(1/fC1)} = \frac{V1 - V2}{R_{EQUIV}}$$

A new variable, R_{EQUIV} , has been defined such that $R_{EQUIV} = 1/fC1$. Thus, the equivalent circuit for the switched capacitor network is as shown in Figure 3.

Figure 3. Switched Capacitor Equivalent Circuit

Examination of Figure 4 shows that the LTC1044 has the same switching action as the basic switched capacitor building block. With the addition of finite switch on-resistance and output voltage ripple, the simple theory, although not exact, provides an intuitive feel for how the device works.

Figure 4. LTC1044 Switched Capacitor Voltage Converter Block Diagram

For example, if you examine power conversion efficiency as a function of frequency (see typical curve), this simple theory will explain how the LTC1044 behaves. The loss, and hence the efficiency, is set by the output impedance. As frequency is decreased, the output impedance will eventually be dominated by the $1/fC1$ term and power efficiency will drop. The typical curves for power efficiency versus frequency show this effect for various capacitor values.

Note also that power efficiency decreases as frequency goes up. This is caused by internal switching losses which occur due to some finite charge being lost on each switching cycle. This charge loss per unit cycle, when multiplied by the switching frequency, becomes a current loss. At high frequency this loss becomes significant and the power efficiency starts to decrease.

LV (Pin 6)

The internal logic of the LTC1044 runs between V^+ and LV (pin 6). For V^+ greater than or equal to 3V, an internal switch shorts LV to GND (pin 3). For V^+ less than 3V, the LV pin should be tied to GND. For V^+ greater than or equal to 3V, the LV pin can be tied to GND or left floating.

APPLICATIONS INFORMATION

OSC (Pin 7) and Boost (Pin 1)

The switching frequency can be raised, lowered or driven from an external source. Figure 5 shows a functional diagram of the oscillator circuit.

By connecting the boost pin (pin 1) to V^+ , the charge and discharge current is increased and, hence, the frequency is increased by approximately 7 times. Increasing the frequency will decrease output impedance and ripple for higher load currents.

Loading pin 7 with more capacitance will lower the frequency. Using the boost (pin 1) in conjunction with external capacitance on pin 7 allows user selection of the frequency over a wide range.

Driving the LTC1044 from an external frequency source can be easily achieved by driving pin 7 and leaving the boost pin open, as shown in Figure 6. The output current from pin 7 is small, typically $0.5\mu\text{A}$, so a logic gate is capable of driving this current. The choice of using a CMOS logic gate is best because it can operate over a wide supply voltage range (3V to 15V) and has enough voltage swing to drive the internal Schmitt trigger shown

in Figure 5. For 5V applications, a TTL logic gate can be used by simply adding an external pull-up resistor (see Figure 6).

External Diode (D_x)

Previous circuits of this type have required a diode between V_{OUT} (pin 5) and the external capacitor, C_2 , for voltages above 6.5V (5V for military temperature range). Because of improvements which have been made in the LTC1044 circuit design and Linear Technology's silicon gate CMOS process, this diode is no longer required. The LTC1044 will operate from 1.5V to 9V, without the protection diode, over all temperature ranges.

It should, however, be noted that the LTC1044 will operate without any problems in existing 7660 designs which use the protection diode, as long as the maximum operating voltage (V^+) of 9V is not exceeded.

Capacitor Selection

External capacitors C_1 and C_2 are not critical. Matching is not required, nor do they have to be high quality or tight tolerance. Aluminum or tantalum electrolytics are excellent choices, with cost and size being the only consideration.

Figure 5. Oscillator

Figure 6. External Clocking

TYPICAL APPLICATIONS

Negative Voltage Converter

Figure 7 shows a typical connection which will provide a negative supply from an available positive supply. This circuit operates over full temperature and power supply ranges *without* the need of any external diodes. The LV pin (pin 6) is shown grounded, but for $V^+ \geq 3V$ it may be "floated", since LV is internally switched to ground (pin 3) for $V^+ \geq 3V$.

The output voltage (pin 5) characteristics of the circuit are those of a nearly ideal voltage source in series with an 80Ω resistor. The 80Ω output impedance is composed of two terms: 1) the equivalent switched capacitor resistance (see Theory of Operation) and 2) a term related to the on-resistance of the MOS switches.

At an oscillator frequency of $10kHz$ and $C1 = 10\mu F$, the first term is:

$$R_{EQUIV} = \frac{1}{(f_{OSC}/2) \times C1} = \frac{1}{5 \times 10^3 \times 10 \times 10^{-6}} = 20\Omega.$$

Notice that the above equation for R_{EQUIV} is *not* a capacitive reactance equation ($X_C = 1/\omega C$) and does not contain a 2π term.

The exact expression for output impedance is extremely complex, but the dominant effect of the capacitor is clearly shown on the typical curves of output impedance and power efficiency versus frequency. For $C1 = C2 = 10\mu F$, the output impedance goes from 60Ω at $f_{OSC} = 10kHz$ to 200Ω at $f_{OSC} = 1kHz$. As the $1/fC$ term becomes large compared to the switch on-resistance term, the output resistance is determined by $1/fC$ only.

Voltage Doubling

Figure 8 shows two methods of voltage doubling. In Figure 8a doubling is achieved by simply rearranging the connection of the two external capacitors. When the input voltage is less than $3V$, an external $1M\Omega$ resistor is required to ensure the oscillator will start. It is not required for higher input voltages.

In this application the ground input (pin 3) is taken above V^+ (pin 8) during turn-on, making it prone to latch-up. The latch-up is not destructive but simply prevents the circuit from doubling. Resistor $R1$ is added to eliminate the problem. In most cases 200Ω is sufficient. It may be necessary in a particular application to increase this value to guarantee start-up.

The voltage drop across $R1$ is: $V_{R1} = 2 \times I_{OUT} \times R1$. If this voltage exceeds two diode drops ($1.4V$ for silicon, $0.8V$ for Schottky), the circuit in Figure 8a is recommended. This circuit will never have a start-up problem.

Figure 7. Negative Voltage Converter

(a)

(b)

Figure 8. Voltage Doubler

TYPICAL APPLICATIONS

Ultra Precision Voltage Divider

An ultra precision voltage divider is shown in Figure 9. To achieve the 0.0002% accuracy indicated, the load current should be kept below 100nA. However, with a slight loss in accuracy, the load current can be increased.

Battery Splitter

A common need in many systems is to obtain (+) and (–) supplies from a single battery or single power supply system. Where current requirements are small, the circuit shown in Figure 10 is a simple solution. It provides symmetrical $\pm$ output voltages, both equal to one half the input voltage. The output voltages are both referenced to pin 3 (output common). If the input voltage between pin 8 and pin 5 is less than 6V, pin 6 should also be connected to pin 3, as shown by the dashed line.

Paralleling for Lower Output Resistance

Additional flexibility of the LTC1044 is shown in Figures 11, 12 and 13.

Figure 9. Ultra Precision Voltage Divider

Figure 11 shows two LTC1044s connected in parallel to provide a lower effective output resistance. If, however, the output resistance is dominated by $1/fC_1$, increasing the capacitor size (C1) or increasing the frequency will be of more benefit than the paralleling circuit shown.

Figures 12 and 13 make use of "stacking" two LTC1044s to provide even higher voltages. In Figure 12, a negative voltage doubler or tripler can be achieved, depending upon how pin 8 of the second LTC1044 is connected, as shown schematically by the switch. Figure 13 indicates a similar circuit which can be used to obtain positive tripling, or even quadrupling (the doubler circuit appears in Figure 8a). In both of these circuits, the available output current will be dictated/decreased by the product of the individual power conversion efficiencies and the voltage step-up ratio.

Precision Sample and Hold Amplifier

FEATURES

- *Guaranteed* 6 μ s Max. Acquisition Time
- *Guaranteed* 0.005% Max. Gain Error
- *Guaranteed* 1mV Max. Offset Voltage
- *Guaranteed* 1mV Max. Hold Step
- Very Low Feedthrough 86dB Min.
- High Input Impedance under All Conditions
- Logic Inputs Compatible with All Logic Families

APPLICATIONS

- 12-Bit Data Acquisition Systems
- Ramp Generators
- Analog Switches
- Staircase Generators
- Sample and Difference Circuits

DESCRIPTION

The LF198 is a precision sample and hold amplifier which uses a combination of bipolar and junction FET transistors to provide precision, high speed, and long hold times. A typical offset voltage of 1mV and gain error of 0.002% allow this sample and hold amplifier to be used in 12-bit systems. Dynamic performance can be optimized by proper selection of the external hold capacitor. Acquisition times can be as low as 4 μ s for small capacitors while hold step and droop errors can be held below 0.1mV and 30 μ V/sec respectively when using larger capacitors.

The LF198 is fixed at unity gain with 10¹⁰ Ω input impedance independent of sample/hold mode. The logic inputs are high impedance differential to allow easy interfacing to any logic family without ground loop problems. A separate offset adjust pin can be used to zero the offset voltage in either the sample or hold mode. Additionally, the hold capacitor can be driven with an external signal to provide precision level shifting or "differencing" operation. The device will operate over a wide supply voltage range from ± 5 V to ± 18 V with very little change in performance, and key parameters are specified over this full supply range.

The LF198A version offers tightened electrical specifications for key parameters.

The • denotes the specifications which apply over the full operating temperature range.

Note 1: T_J max for the LF198/LF198A is 150°C; T_J max for the LF398/LF398A is 100°C.

Note 2: The logic inputs are protected to ±30V differential as long as the voltage on both pins does not exceed the supply voltage. For proper operation, however, both logic and logic reference pins must be at least 2V below the positive supply and one of these pins must be at least 3V above the negative supply.

Note 3: Unless otherwise noted, V_S = ±15V, T_J = 25°C, -11.5V ≤ V_{IN} ≤ +11.5V, C_h = 0.01μF, R_L = 10kΩ and unit is in "sample" mode. Logic reference = 0V and logic voltage = 2.5V.

Note 4: The hold step is sensitive to stray capacitance coupling between input logic signals and the hold capacitor. 1pF, for instance, will create an additional 0.5mV step with a 5V logic swing and a 0.01μF hold capacitor. Magnitude of the hold step is inversely proportional to hold capacitor value.

Note 5: Leakage current is measured at a junction temperature of 25°C. The effects of junction temperature rise due to power dissipation or elevated ambient can be calculated by doubling the 25°C value for each 11°C increase in chip temperature. Leakage is guaranteed over full input signal range.

Note 6: These parameters are guaranteed over a supply voltage range of ±5V to ±18V.

APPLICATIONS INFORMATION

Hold Capacitor

For fast sample and hold applications, the size of the hold capacitor is critical. A low value will give fast acquisition, but will also increase errors due to hold step, and droop caused by amplifier bias current. The capacitor should be made as large as possible, consistent with acquisition time and dynamic sampling error requirements. Capacitors larger than $0.1\mu\text{F}$ have an additional problem. They are generally not available in the low loss dielectrics like Teflon, Polystyrene, and NPO, at least not at a reasonable price and size. Mylar, even with its poor dielectric absorption properties, may be a reasonable choice where very long sample times are used and low droop rates are needed.

Dielectric absorption in the hold capacitor can often be the major source of error in a sample and hold. The equivalent "circuit" of a typical capacitor is shown below with parallel RC networks used to model dielectric absorption.

Typical Hold Capacitor Equivalent Circuit

$C_a, C_b \approx 0.01$ TO $0.1 C_h$
 R_a, R_b GENERATE TIME CONSTANTS
OF 0.1-50 MILLISECONDS WITH C_a, C_b

One can see that rapid changes in capacitor voltage will not be tracked by the internal parasitic capacitors because of the resistance in series with them. This leads to a "sag" effect in the hold capacitor after a sudden change in voltage followed by rapid switch to the hold mode. The capacitor remembers its previous state via the charge on the internal parasitic capacitance and sags

APPLICATIONS INFORMATION

back slightly toward the previous voltage. The magnitude of the sag depends on the voltage change and the time spent sampling the new voltage. Several time constants are typically evident in the sag, although some capacitors tend to exhibit a single time constant, while others show a sag that indicates a blending of many time constants. The curves labeled CAPACITOR DIELECTRIC ABSORPTION show the amount of sag found after a 10V step with sample time at the new voltage and hold time at the new voltage as variables. It is obvious that sag problems are minimized by long sample times and short hold times. This is often in conflict with basic sampling requirements, but one point should be made: if at all possible, keep the sample and hold amplifier in the "tracking", or sampling, mode as much as possible to maximize the time the hold capacitor spends near the voltage at which it will eventually "hold".

The best capacitor for sample and hold applications is Teflon. It is clearly superior with regard to dielectric absorption and operates over the full -55°C to 125°C temperature range. If size or price becomes a problem, the second choice for full temperature range operation is "NPO", or "COG" ceramic units. Some care must be used here—not all NPO capacitors use the low dielectric constant ceramic necessary for low dielectric absorption. For lower temperatures ($\leq 70^{\circ}\text{C}$), Polystyrene has traditionally been the best hold capacitor. The best units are cylindrical and fairly large—there seems to be a strong correlation between small size and poorer dielectric performance. Polypropylene has nearly the same absorption properties as polystyrene and offers 85°C operation. It also tends to be smaller. Again, stay with cylindrically wrapped units. Other standard dielectrics such as mica, glass, mylar, and ordinary ceramic are much worse with regard to dielectric absorption. Mylar is sometimes used for large values when the ratio of sample to hold time is large and extremely low droop is required.

Dynamic Sampling Error

A significant sampling error can occur in any sample and hold if the input is moving when the unit is put into the hold mode. The two major causes for this error are digital delay in switch opening and analog delay across the hold capacitor.

The switch opening delay is obvious and leads to a "held" output error of $(dv/dt) \times (T_d)$, where dv/dt is the slew rate of the input signal and T_d is switch delay. In the case of the LF198, T_d is approximately 150ns, giving a 4.5mV error when sampling the zero crossing of a 5V (peak) sine wave at 1kHz ($dv/dt = A \cdot 2\pi f = 5 \cdot 2\pi \cdot 10^3$). The analog delay is the difference between input signal and capacitor voltage. It is determined by the RC product of the hold capacitor and the effective series resistance, which in the case of the LF198 is about 150Ω . This analog delay with a $0.01\mu\text{F}$ hold capacitor is $R \cdot C = 150 \times 10^{-8} = 1.5\mu\text{s}$, or about ten times the delay of the switch. The sign of the analog delay is negative—the held output is related in time to the input voltage *before* the hold command was given. The overall dynamic sampling error is the sum of the digital and analog errors. The curve labeled *Dynamic Sampling Error* will be helpful in estimating these errors as a function of input slew rate and hold capacitor size.

Dynamic sampling error can be reduced by a factor of ten or more by inserting a delay in the logic input so that the "hold" command is delayed by an amount equal to the RC time constant of the LF198 and external hold capacitor. For a $0.01\mu\text{F}$ hold capacitor and the 150Ω resistor internal to the LF198, this is $1.5\mu\text{s}$. A simple RC network can be used in front of the logic input for delays up to $\approx 1\mu\text{s}$. Longer delays require the addition of a logic gate to speed up the rise time of the delayed signal. See LOGIC RISE TIME in this section for further details.

Hold Step

Hold step is the small voltage step (after settling) seen at the output of a sample and hold amplifier when it is switched from the sample mode to the hold mode with a steady DC input. Hold step is typically the result of, or can be modeled as, a fixed quantity of charge transferred to the hold capacitor as a result of the internal switching that occurs during the hold command. In the case of the LF198, that charge is about 5 picocoulombs, giving a hold step of 0.5mV for a $0.01\mu\text{F}$ hold capacitor and 5mV for a 1000pF hold capacitor. ($V = Q/C$.) Hold step is reasonably independent of logic amplitude if care is taken to minimize the stray capacitance between the logic input

APPLICATIONS INFORMATION

and the hold capacitor. With thoughtful layout, including the guarding technique shown below, stray capacitance should be under 0.3pF, limiting charge variations to less than 0.3 picocoulombs per volt.

Guarding Technique

Use 10-pin layout. Guard around C_H is tied to output.

Hold step varies slightly with analog input voltage (see curves). A typical unit will change at 0.4 picocoulombs per volt. This manifests itself as a gain error when the amplifier is switched to the hold mode. With a $0.01\mu\text{F}$ capacitor, the resulting gain error will be $(0.4 \text{ PC/V}) / 0.01\mu\text{F} = 0.004\%$. This gain error is in the opposite direction of DC (sample mode) gain error. At high values of hold capacitor, DC gain error will dominate and gain will be slightly below unity (0.002%). For low value capacitors ($< 0.01\mu\text{F}$), hold step induced gain error will dominate and hold mode gain will be slightly above unity. Zeroing out hold step does not change the variation of hold step with regard to input voltage.

Offset Zeroing

A sample and hold amplifier has two distinct offset voltages. The first is just the DC offset of the amplifier while in the sample or "tracking" mode. It is identical to the input offset of any operational amplifier. The second offset voltage is the sum of the DC offset plus a dynamic term called hold step. Hold step is a change in output voltage when the amplifier is switched from sample mode to hold mode, with the input held steady. This second offset is often called hold mode offset. It can be less than or much greater than the DC offset, depending on the magnitude and sign of hold step.

A fairly accurate model for hold step is a fixed charge injected into the hold capacitor by the switch turn-off circuitry. The magnitude of the charge is reasonably independent of logic input amplitude. The resulting change in hold capacitor voltage is Q/C_H . The charge, Q , is typically 5 picocoulombs, giving a 0.5mV hold step with a $0.01\mu\text{F}$ hold capacitor. Since most sample and hold amplifiers are "used," i.e., have their outputs read by an A/D converter, etc., during the hold mode, hold mode offset is arguably much more important than sample mode DC offset.

DC offset adjustment is accomplished with a 1k low TC cermet potentiometer tied to V^+ with 0.6mA flowing through it and the wiper tied to pin 2. This allows pin 2 to be moved $\pm 300\text{mV}$ around its nominal voltage (0.3V below V^+). Offset adjustment range is $\pm 9\text{mV}$, and the adjustment procedure nominally improves offset drift when the DC offset is reduced to zero. This offset method *can* be used to zero out hold mode offset, but at the expense of some induced offset drift. Each millivolt of hold step offset that is corrected by this method introduces $3.3\mu\text{V}/^\circ\text{C}$ drift. For $0.002\mu\text{F}$ or larger hold capacitors where hold step is a few millivolts or less, this is a practical solution to hold mode offset. In precision wide temperature range applications, or where C_H is less than $0.002\mu\text{F}$, a separate hold mode zeroing method should be used. The circuit shown in the application section using a logic inverter and a 5pF capacitor is recommended (DC AND AC ZEROING).

APPLICATIONS INFORMATION

Logic Fall Time

Hold step is independent of logic input fall time only for fall times faster than $10V/\mu s$. For instance, as logic fall time changes from $10V/\mu s$ to $1V/\mu s$, hold step with a $0.01\mu F$ hold capacitor will typically increase from $0.25mV$ to $1.0mV$. See the curve labeled HOLD STEP vs LOGIC SLEW RATE for further data points. If logic slew rate is not constant, use the value at the threshold point ($1.5V$ with respect to logic reference). An RC network will have a discharge slew rate of V_L/RC , where V_L is the logic threshold of the LF198. The delay generated by the network will be $RC \ln(V^+/V_L)$, where V^+ is logic amplitude. For a $1\mu s$ delay, with $5V$ logic, an RC time constant of $0.8\mu s$ is needed. This has a slew rate of $2V/\mu s$ at threshold, which will slightly degrade hold step. It is obvious that an RC delay network significantly longer then

$1\mu s$ will have a large effect on hold step. If longer delays are required, they should be followed by several inverter stages or a Schmitt trigger to increase slew rate.

Adding Delay to Logic Input

LOGIC INPUT CONFIGURATIONS*

TTL and CMOS
 $3V \leq V_L$ (Hi State) $\leq 10V$

DEFINITION OF TERMS

Hold Step: The voltage step at the output of the amplifier when switching from sample mode to hold mode with a constant analog input voltage and a logic swing of 5V.

Acquisition Time: The time required to acquire, within a defined error, a new analog input voltage with an output change of 10V. Acquisition time includes output settling time and includes the time required for all internal nodes to settle so that the output is at the proper value when switched to the hold mode.

Gain Error: The ratio of output voltage swing to input voltage swing in the sample mode expressed as a percent difference.

Hold Settling Time: The time required for the output to settle within 1mV of final value after a hold command is initiated.

Dynamic Sampling Error: The error introduced into the held output voltage due to a changing analog input at the time the hold command is given. Error is expressed in mV with a given hold capacitor value and input slew rate. Note that this error term occurs even for long sample times.

Aperture Time: The delay required between "Hold" command and an input analog transition, so that the transition does not affect the held output.

FEATURES

- Low Operating Voltage $\pm 5V$ to $\pm 15V$
- 500 μA Supply Current
- Zero Supply Current when Shut Down
- Outputs Can Be Driven $\pm 30V$
- Thermal Limiting
- Output "Open" when Off
- 10mA Output Drive
- Pin Compatible with 1488

APPLICATIONS

- RS232 Driver
- Power Supply Inverter
- Micropower Interface
- Level Translator

DESCRIPTION

The LT1032 is a RS232 and RS423 line driver that operates over a $\pm 5V$ to $\pm 15V$ range on low supply current and can be shut down to zero supply current. Outputs are fully protected from externally applied voltages of $\pm 30V$ by both current and thermal limiting. Since the output swings to within 200mV of the positive supply and 600mV of the negative supply, power supply needs are minimized.

Also included is a strobe pin to force all outputs low independent of input or shutdown conditions. Further, slew rate can be adjusted with a resistor connected to the supply.

A major advantage of the LT1032 is the high impedance output state when off or powered down.

TYPICAL APPLICATION

*NO CONNECTION NEEDED WHEN NOT USED.

[†]5V = ON.

APPLICATIONS INFORMATION

Application Hints

The LT1032 is exceptionally easy to use when compared to older drivers. Operating supply voltage can be as low as $\pm 3V$ or as high as $\pm 15V$. Input levels are referred to ground.

The logic inputs are internally set at TTL levels. Outputs are valid for input voltages from 1V above V^- to 25V. Driving the logic inputs to V^- turns off the output stage. The "on-off" control completely turns off all supply current of the LT1032. The levels required to drive the device on or off are set by internal emitter-base voltages. Since the current into the "on-off" pin is so low, TTL or CMOS drivers have no problem controlling the device.

The strobe pin is not fully logic compatible. The impedance of the strobe pin is about $2k\Omega$ to ground. Driving the strobe pin positive forces the output stages low—even if the device is shut off. Under worst-case conditions, 3V minimum at 2mA are needed driving the strobe pin to insure strobing.

The response pin can be used to make some adjustment in slew rate. A resistor can be connected between the response pin and the power supplies to drive $50\mu A$ to $100\mu A$ into the pin. The response pin is a low impedance point operating at about 0.75V above ground. For supply voltage up to $\pm 6V$, current is turned off when the device is turned off. For higher supply voltages, a zener should be connected in series with the resistor to limit the voltage applied to the response pin to 6V. Also, for temperatures above $100^\circ C$, using the response pin is not recommended. The leakage current into the response pin at high temperatures is excessive.

Outputs are well protected against shorts or externally applied voltage. Tested limits are $\pm 30V$, but the device can withstand external voltages up to the breakdown of the transistors (typically about 50V). The LT1032 is usually immune to ESD up to 2500V on the outputs with no damage (limit of LTC tester).

PIN FUNCTION

PIN	FUNCTION	COMMENT
1	Minus Supply	Operates $-2V$ to $-15V$
2,5,9,12	Logic Input	Operates properly on TTL or CMOS levels. Output valid from $(V^- + 2V) \leq V_{IN} \leq 15V$. Connect to ground when not used.
3,6,8,11	Output	Line drive output.
4	On-Off	Shuts down entire circuit. Cannot be left open. For "normally on" operation, connect to V^+ .
7	Ground	Ground must be more positive than V^-
10	Response Control	Allows limited change of slew rate. Leave open when not used.
13	Strobe	Forces all outputs low. Drive with 3V.

LINEAR TECHNOLOGY MIL/JAN PRODUCTS

Linear Technology Corporation offers a comprehensive selection of precision voltage references, operational amplifiers, voltage regulators, comparators, and CMOS circuits designed specifically to serve the rigorous requirements of the military marketplace.

The company's specification system and quality procedures and policies were set up from the beginning to meet the exacting demands of MIL-Q-9858 (Quality Program Requirements), MIL-I-45208 (Inspection System Requirements), MIL-M-38510 (General Specification For Microcircuits) and MIL-STD-883 (Test Methods and Procedures For Microelectronics).

Compliance to these specifications is a statutory requirement for all employees at Linear Technology. The programs now in place that serve the varied requirements for ground, sea, air, and space applications include:

- JAN
- DESC Drawings
- Hi-Rel (SCD)
- 883

Linear Technology JAN

At the end of 1969, the Solid State Applications Branch of the Rome Air Development Center (RADC) issued the first copy of MIL-M-38510. This general specification for microcircuits established the procedures that a manufacturer must follow to have his products listed on the Qualified Parts List (QPL).

One major problem faced by defense contractors using semiconductor devices was the inability to interchange devices caused by a proliferation of non-standard electrical specifications. The 38510 (JAN) program addressed this problem by publishing detailed electrical specifications (slash sheets) for each component to be listed on the QPL.

JAN devices are completely processed in the United States or its territories and all wafer fabrication, wafer sort, assembly, testing, and conformance testing are performed onshore.

In early 1985, Linear Technology Corporation joined the ranks of the eighteen existing QPL suppliers. Of these eighteen, only a handful of suppliers participate in the linear military JAN market. Linear Technology believes its analog design experience and manufacturing strength can contribute significantly to this market.

In August 1984, Linear Technology Corporation was visited by a team of DESC (Defense Electronics and Supply Center) personnel. This team spent almost four days on their audit and at the end of the visit they awarded the company "line certification". *This was a first for any company to receive this distinction on a first audit!*

Linear Technology's first QPL listing was achieved in February, 1985, one year after the company made JAN Class B a corporate goal. Other companies have typically taken 2 to 3 years to achieve this status. The line certification and QPL approvals were awarded to the new MIL-38510 Rev. F and MIL-STD-883 Rev. C specifications.

Linear Technology's policy of providing JAN Class B linear components supports the United States Government's position of standardization to decrease the number of active part types maintained by DESC. This number is currently in excess of 70,000 for all types of components (contrasted to approximately 5,000 industry standard components). Standardization will clearly decrease costs and assist in the maintenance of military weapon systems and equipment now in the field. By the end of 1985, the company plans to have at least 6 devices on the Qualified Parts List and we have an active program to pursue more qualifications in the future.

EXAMPLES OF LINEAR TECHNOLOGY MILITARY PROGRAM PARTICIPATION

AMRAAM	SPARROW	PERSHING II
PHOENIX	HARPOON	MINUTEMAN
PHALANX	HARM	B-1B
F-15	COPPERHEAD	B-52

F-18	HTTB	MAVERICK
DRAGON	SEAHAWK	ACTS
STD. MISSILE	FLEET SATCOM	M-1 TANK

Linear Technology DESC Drawings

DESC drawings were initiated in 1976 to standardize the electrical requirements for full temperature-tested military components. These DESC drawings (or minispecs) were initially issued for low power Schottky devices (54LS) used by defense subcontractors on the Air Force's F16. The program accomplished standardization of testing, without the delays associated with the qualification process for JAN components.

The DESC drawing was viewed as a preliminary specification prior to JAN approval, and it ranks second in the order of purchasing hierarchy to JAN. This order is defined in Requirement 64 of MIL-STD-454. If a JAN part is available, it is still preferred, however, there are many types of devices where the volume is such that the cost of a full JAN qualification may not be justified, but where a need exists for electrical standardization.

CMOS and analog circuits were added to the DESC Drawing Program in 1977, 1978 and 1979, but widespread acceptance of these parts was not achieved. Today with more emphasis being placed on standardization, the interest level in DESC drawings has accelerated. This category of product can be built offshore with 883-level processing and the electrical parameters are tested specifically to the DESC drawing.

To provide parts to a DESC drawing, a manufacturer has to have at least one part on the 38510 Qualified Parts List. He must also provide DESC with a certificate of compliance agreeing to the tests and conditions listed on the drawing.

Linear Technology has a number of devices listed on DESC drawings, and we are actively supporting this program by having parts available off the shelf from Linear Technology Corporation and from distribution outlets.

Linear Technology Hi-Rel

Linear Technology Corporation recognizes the need for source controlled drawings (SCD's) and the company's DESC-certified line is well equipped to handle these requirements for hi-rel applications. The company has a comprehensive review procedure and emphasis is placed on compliance to test methods and procedures. Over 1,200 specifications have been reviewed to date with fast feedback to our customers.

Linear Technology has serviced source controlled drawing orders including "S" level specifications with a variety of source inspection and conformance test requirements. Each source controlled drawing requires dedicated flows, software and hardware, and as a result, certain minimum requirements have to be fulfilled. Linear Technology's Product Marketing group can provide you with more details on a case-by-case basis.

Linear Technology MIL-STD-883 Product

The semiconductor industry 883 designation on military semiconductor components established a defacto standard in response to a significant demand from the military defense contractors. The Government recognized the existence of 883 components in the recent revisions of MIL-STD-883C and MIL-M-38510F, and the requirements for compliant 883 components are now defined very specifically in these documents.

MIL-STD-883 is a test procedures and methods document and the latest revision (Rev. C) became effective on June 1, 1984. Twenty-seven test methods were modified extensively and four new test methods were added. Class C product was eliminated leaving Class B and Class S. Class B is intended for applications where maintenance is difficult or expensive and where reliability is vital. Class S is intended for space and critical applications where replacement is extremely difficult or impossible and where reliability is imperative. The Class B PDA (Percent Defective Allowable) was tightened from 10% to 5% following burn-in and the Group A electrical sampling plans (LTPD levels) also were tightened. In addition, a critical paragraph was added to MIL-STD-883 to alleviate any misinterpretation; a factor that had previously created vastly different 883 programs throughout the semiconductor industry.

On December 31, 1984, another key clause was added to MIL-STD-883 Rev. C, "paragraph 1.2.1." This states that if a manufacturer advertises, certifies, or marks parts as compliant with MIL-STD-883 those parts must meet all of the provisions of MIL-STD-883, a practice consistent with "Truth in Advertising".

According to the Defense Electronics Supply Center (a branch of the Defense Department's Logistics Agency), the intent of paragraph 1.2.1 was to link MIL-STD-883 with the controls and details contained in MIL-M-38510.

Linear Technology Corporation can state unequivocally that all of its 883 products are in full compliance with the new MIL-STD-883 Rev. C requirements. We have over 150 versions of our 883 products listed in our current catalog, including operational amplifiers, voltage regulators, voltage references, comparators, and our advanced line of proprietary CMOS circuits.

All products manufactured by Linear Technology are designed to meet the full requirements of the military, from -55°C to 125°C .

Military Market Commitment

Linear Technology Corporation is a focused, dedicated company servicing the needs of the linear military marketplace. We are shipping to the top U. S. defense electronics contractors who have qualified and approved our products. Linear Technology Corporation is committed to being the best and most proficient high quality supplier of analog military components.

AC Parametric	$T_A = 25^{\circ}\text{C}$	125	.04%	1.8%	116	2.0%

Linear Technology Corporation uses a Group A sampling plan which exceeds the LTPD requirements of the present 883 specification. This ensures an even higher outgoing quality level of Linear Technology product, as is shown in the graph and table above.

Note (1) AQL defined at a 'Probability of Acceptance' of 95%.

Micropower Regulator and Comparator

FEATURES

- 40 μ A Supply Current
- 125mA Output Current
- 2.5V Reference Voltage
- Reference Output Sources 1mA and Sinks 0.5mA
- Dual Output Comparator
- Comparator Sinks 10mA
- Dropout Detector
- 0.2V Dropout Voltage
- Thermal Limiting

DESCRIPTION

The LT1020 is a combination micropower positive regulator and free collector comparator on a single monolithic chip. With only 40 μ A supply current, the LT1020 can supply over 125mA of output current. Input voltage range is from 5V to over 36V and dropout voltage is 0.6V at 125mA. Dropout decreases with lower load currents. Also included on the chip is a class B output 2.5V reference that can either source or sink current. A dropout detector provides an output current to indicate when the regulator is about to drop out of regulation.

The dual output comparator can be used as a comparator for system or battery monitoring. For example, the comparator can be used to warn of low system voltage while the dropout detector shuts down the system to prevent abnormal operation. Frequency compensation of the comparator for amplifier applications can be obtained by adding external output capacitance. Dual output or positive and negative regulators can also be made.

APPLICATIONS

- Battery Systems
- Battery Backup System
- Portable Terminals
- Portable Instruments

1 Amp Low Dropout Regulator

*FOR CURRENT LIMIT

FEATURES

- 3 μ S Settling Time
- 1mV Offset Voltage
- 100nA Bias Current
- 18V/ μ S Slew Rate
- 3MHz Gain Bandwidth

APPLICATIONS

- DAC Output Amplifier
- Fast Inverting Amplifier

DESCRIPTION

The LT1023 is a fast inverting op amp with 18V/ μ S slew rate as well as good DC characteristics. Designed as a DAC output amplifier, the LT1023 settles to 0.1% of a 10V step in a maximum of 3 μ S. The low offset voltage and drift eliminate the need for adjustments in most applications.

Other applications for the LT1023 are fast inverters, oscillators, or audio. Available in packages or dice for hybrids the LT1023 is compatible with the OP-01.

PIN CONNECTIONS

Thermocouple Cold Junction Compensator

FEATURES

- 1°C Accuracy
- Compensates for E, J, K, R, S, T Thermocouples
- 50 μ A Operating Current
- Operates from 3.5V to 40V

APPLICATIONS

- Temperature Measurement
- Controllers
- Sensing

DESCRIPTION

The LT1025 is a monolithic temperature sensor designed to cold-junction compensate a variety of thermocouples. Accuracy is better than 1°C. A 10mV/°C output is provided from the sensing circuitry to a precision thin film divider network. High output accuracy is maintained over a 0°C to 60°C range.

Ultra-Low Noise, High Speed Op Amp

FEATURES

- Voltage Noise @ 1kHz 0.9nV/ $\sqrt{\text{Hz}}$ typ.
- Voltage Noise @ 10Hz 1.1nV/ $\sqrt{\text{Hz}}$ typ.
- Slew Rate 15V/ μs typ.
- Offset Voltage 15 μV typ.
- Bias Current 15nA typ.
- Voltage Gain 5 million typ.

DESCRIPTION

The LT1028 achieves a new low in noise performance with 0.9nV/ $\sqrt{\text{Hz}}$ 1kHz noise, and 35nV peak-to-peak noise from 0.1Hz to 10Hz. This ultra-low noise is combined with excellent high speed specifications (gain bandwidth product is 65MHz), distortion free output, and true precision parameters (0.2 $\mu\text{V}/^\circ\text{C}$ drift). Although the LT1028 input stage operates at 1mA of collector currents to achieve low noise, input bias current is only 15nA.

The LT1028's voltage noise is less than the noise of a 50 Ω resistor. Therefore, even in very low source impedance transducer or audio amplifier applications, the LT1028's contribution to total system noise will be negligible.

Voltage Noise vs Frequency

FEATURES

- Low Operating Voltage $\pm 5V$ to $\pm 15V$
- $500\mu A$ Supply Current
- Zero Supply Current when Shut Down
- Outputs Can Be Driven $\pm 30V$
- Thermal Limiting
- Output "Open" when Off
- 10mA Output Drive
- Pin Compatible with 1488

APPLICATIONS

- RS232 Driver
- Power Supply Inverter
- Micropower Interface
- Level Translator

DESCRIPTION

The LT1030 is an RS232 line driver that operates over a $\pm 5V$ to $\pm 15V$ range on low supply current and can be shut down to zero supply current. Outputs are fully protected from externally applied voltages of $\pm 30V$ by current limiting. Since the output swings to within 200mV of the positive supply and 1V of the negative supply, power supply needs are minimized.

A major advantage of the LT1030 is the high impedance output state when off or powered down.

TYPICAL APPLICATION

RS232 Line Driver

*NO CONNECTION NEEDED WHEN NOT USED.

†5V = ON.

Output Swing vs Output Current

	High Input ($V_{OUT} = \text{Low}$)	2	1.4		V
Logic Input Current	$V_{IN} > 2.0V$		2	20	μA
	$V_{IN} < 0.8V$		10	20	μA
On-Off Pin Current	$0 \leq V_{IN} \leq 5V$	-10	3	50	μA
Slew Rate	$I_{RESPONSE} = 0$	4	15	30	V/ μS

The ● denotes specifications which apply over the operating temperature range.

Note 1: 3V applied to the strobe pin will force all outputs low. Strobe pin input impedance is about 2k to ground. Leave open when not used.

Note 2: Response can be changed by connecting a resistor to the supply. For supplies less than $\pm 6V$ this current is disconnected when shut down. Leave open when not used.

PIN FUNCTIONS

PIN	FUNCTION	COMMENT
1	Minus Supply	Operates $-2V$ to $-15V$
2,5,9,12	Logic Input	Operates properly on TTL or CMOS levels. Output valid from $(V^- + 2V) \leq V_{IN} \leq 15V$. Connect to ground when not used.
3,6,8,11	Output	Line drive output.
4	On-Off	Shuts down entire circuit. Cannot be left open. For "normally on" operation, connect 5V to 10V.
7	Ground	Ground must be more positive than V^-
13	Strobe	Forces all outputs low. Drive with 3V.

Triple RS232 Line Driver and Receiver

FEATURES

- Three Drivers and Receivers
- Low Power
- Shuts Down to Zero Power
- High Impedance Output When Off
- Operates $\pm 5V$ to $\pm 15V$
- Wide Output Swing
- "Keep-Alive" Bias Point
- Overload Protected

APPLICATIONS

The LT1039 is a triple RS232 line driver and line receiver featuring low supply current and shutdown. Operating from $\pm 5V$ to $\pm 15V$, the LT1039 has wide output swing minimizing the supply requirements. Outputs can be overdriven up to $\pm 30V$. The receiver accepts standard RS232 levels up to $\pm 30V$ input. The receiver output is compatible with CMOS or TTL.

Two unique features available on the LT1039 make it more useful. The shutdown completely turns off the LT1039 decreasing supply current to zero. Also, the output goes to a high impedance state allowing devices to be paralleled. A bias pin allows one of the receivers to be powered up while the rest of the LT1039 is shut down. This receiver could then be used to power up the rest of the LT1039 in response to an external control.

Dual, JFET Input, Precision High Speed Op Amp Quad, JFET Input, Precision High Speed Op Amp

FEATURES

- 13V/ μ s Slew Rate
- 5MHz Gain Bandwidth Product
- 250 μ V Offset Voltage (LT1073)
- 500 μ V Offset Voltage (LT1074)
- 2 μ V/ $^{\circ}$ C Drift
- 80pA Bias Current at 70 $^{\circ}$ C

DESCRIPTION

The LT1057 is a matched JFET input dual op amp in the industry standard 8 pin DIP configuration, featuring a combination of outstanding high speed and precision specifications. It replaces all the popular bipolar and JFET input dual op amps. In particular, the LT1057 upgrades the performance of systems using the LF412A and OP-215 JFET input duals.

The LT1058 is the first precision quad JFET input operational amplifier in the standard 14 pin DIP configuration. It offers significant accuracy improvements over presently available JFET input quad operational amplifiers.

5A High Efficiency Switching Regulator

FEATURES

- Wide Input Voltage Range 3V–60V
- Low Quiescent Current—6mA
- Internal 5A Switch
- Very Few External Parts Required
- Self-Protected Against Overloads
- Operates in Nearly All Switching Topologies
- Shutdown Mode Draws Only 50 μ A Supply Current
- Flyback-Regulated Mode has Fully Floating Outputs
- Comes in Standard 5-Pin Packages

APPLICATIONS

- Logic Supply 5V @ 10A
- +5V Logic to $\pm$ 15V Op Amp Supply
- Offline Converter up to 200W
- Battery Upconverter
- Power Inverter (+ to –) or (– to +)
- Fully Floating Multiple Outputs

DESCRIPTION

The LT1070 is a monolithic high power switching regulator. It can be operated in all standard switching configurations including buck, boost, flyback, forward, inverting and "Cuk". A 5 amp high efficiency switch is included on the die along with all oscillator, control, and protection circuitry. Integration of all functions allows the LT1070 to be built in a standard 5-pin TO-3 or TO-220 power package. This makes it extremely easy to use and provides "bust proof" operation similar to that obtained with 3-pin linear regulators.

The LT1070 operates with supply voltages from 3V to 60V, and draws only 6mA quiescent current. It can deliver load power up to 100 watts with no external power devices. By utilizing current-mode switching techniques, it provides excellent AC and DC load and line regulation.

The LT1070 has many unique features not found even on the vastly more difficult to use low power control chips presently available. It uses adaptive anti-sat switch drive to allow very wide ranging load currents with no loss in efficiency. An externally activated shutdown mode reduces total supply current to 50 μ A for standby operation. Totally isolated and regulated outputs can be generated by using the optional "flyback regulation mode" built into the LT1070, without the need for opto-couplers or extra transformer windings.

The LT1070 can also be used as an off-line converter by driving an external MOSFET, with power levels up to 300W.

BLOCK DIAGRAM

LT1070 OPERATION

The LT1070 is a current mode switcher. This means that switch duty cycle is directly controlled by switch current rather than by output voltage. Referring to the block diagram, the switch is turned "ON" at the start of each oscillator cycle. It is turned "OFF" when switch current reaches a predetermined level. Control of output voltage is obtained by using the output of a voltage sensing error amplifier to set current trip level. This technique has several advantages. First, it has immediate response to input voltage variations, unlike ordinary switchers which have notoriously poor line transient response. Second, it eliminates the 90° phase shift at midfrequencies in the energy storage inductor. This greatly simplifies closed loop frequency compensation under widely varying input voltage or output load conditions. Finally, it allows simple pulse-by-pulse current limiting to provide maximum switch protection under output overload or short conditions. A low-dropout internal regulator provides a 2.3V supply for all internal circuitry on the LT1070. This low-dropout design allows input voltage to vary from 2.5V to 60V with virtually no change in device performance. A 40kHz oscillator is the basic clock for all internal timing. It turns "ON" the output switch via the logic and driver circuitry. Special adaptive anti-sat circuitry detects onset of saturation in the power switch

and adjusts driver current instantaneously to limit switch saturation. This minimizes driver dissipation and provides very rapid turn-off of the switch.

A 1.2V bandgap reference biases the positive input of the error amplifier. The negative input is brought out for output voltage sensing. This feedback pin has a second function; when pulled low with an external resistor, it programs the LT1070 to disconnect the main error amplifier output and connects the output of the flyback amplifier to the comparator input. The LT1070 will then regulate the value of the flyback pulse with respect to the supply voltage. This flyback pulse is directly proportional to output voltage in the traditional transformer coupled flyback topology regulator. By regulating the amplitude of the flyback pulse, the output voltage can be regulated with no direct connection between input and output. The output is fully floating up to the breakdown voltage of the transformer windings. Multiple floating outputs are easily obtained with additional windings. A special delay network inside the LT1070 ignores the leakage inductance spike at the leading edge of the flyback pulse to improve output regulation.

LT1070 OPERATION

The error signal developed at the comparator input is brought out externally. This pin (V_C) has four different functions. It is used for frequency compensation, current limit adjustment, soft starting, and total regulator shutdown. During normal regulator operation this pin sits at a voltage between 0.9V (low output current) and 2.0V (high output current). The error amplifiers are current output (G_m) types, so this voltage can

be externally clamped for adjusting current limit. Likewise, a capacitor coupled external clamp will provide soft start. Switch duty cycle goes to zero if the V_C pin is pulled to ground through a diode, placing the LT1070 in an idle mode. Pulling the V_C pin below 0.15V causes total regulator shutdown, with only 50 μ A supply current for shutdown circuitry biasing.

PRELIMINARY

LT1071

2.5A High Efficiency Switching Regulator

FEATURES

- Wide Input Voltage Range 3V–60V
- Low Quiescent Current—6mA
- Internal 2.5A Switch
- Very Few External Parts Required
- Self-Protected Against Overloads
- Operates in Nearly All Switching Topologies

- Flyback-Regulated Mode has Fully Floating Outputs
- Comes in Standard 5-Pin Packages

APPLICATIONS

- Logic Supply 5V @ 5A
- +5V Logic to ± 15 V Op Amp Supply
- Offline Converter up to 100W
- Battery Upconverter
- Power Inverter (+ to –) or (– to +)
- Fully Floating Multiple Outputs

DESCRIPTION

The LT1071 is a monolithic high power switching regulator. It can be operated in all standard switching configurations including buck, boost, flyback, forward, inverting and “Cuk”. A 2.5 amp high efficiency switch is included on the die along with all oscillator, control, and protection circuitry. Integration of all functions allows the LT1071 to be built in a standard 5-pin TO-3 or TO-220 power package. This makes it extremely easy to use and provides “bust proof” operation similar to that obtained with 3-pin linear regulators.

The LT1071 operates with supply voltages from 3V to 60V, and draws only 6mA quiescent current. It can deliver load power up to 50 watts with no external power devices. By utilizing current-mode switching techniques, it provides excellent AC and DC load and line regulation.

The LT1071 has many unique features not found even on the vastly more difficult to use low power control chips presently available. It uses adaptive anti-sat switch drive to allow very wide ranging load currents with no loss in efficiency. An externally activated shutdown mode reduces total supply current to 50 μ A for standby operation. Totally isolated and regulated outputs can be generated by using the optional “flyback regulation mode” built into the LT1071, without the need for opto-couplers or extra transformer windings.

The LT1071 can also be used as an off-line converter by driving an external MOSFET, with power levels up to 150W.

**Hex Universal Level
Translator (ULT™)/RS232 Receiver****FEATURES**

- Programmable Power/Speed
- Translate Any Input Voltage to Any Output Voltage
- Power Can Be Completely Shut Off
- Three-State Outputs
- Output Latch Included

DESCRIPTION

The LTC1045 is a CMOS circuit consisting of six high speed comparators with output latches and three-state capability. The comparator's bias current can be easily programmed, with an external resistor, to trade off power consumption and speed. When power is shut off the outputs are latched and continuously available.

With external current limit resistors the inputs can be driven above and below the power supplies making the LTC1045 ideal for us as an RS232 line receiver.

ULT™ is a trademark of Linear Technology Corp.

High Performance Triple Universal Filter Building Block

FEATURES

- Up to 6th Order Filter Functions with a Single 20 Pin 0.3" Wide Package
- Center Frequency Range up to 35kHz
- $f_0 \times Q$ Product Up to 1 MHz
- *Guaranteed* Center Frequency and Q Accuracy Over Temperature
- *Guaranteed* Low Offset Voltages Over Temperature
- 90dB Dynamic Range
- Filter Operates From Single 4.7V Supply and Up to $\pm 8V$ Supplies
- *Guaranteed* Filter Specifications with $\pm 5V$ Supply and $\pm 2.37V$ Supply
- Low Power
- Clock Inputs T²L and CMOS Compatible

APPLICATIONS

- High Order, Wide Frequency Range Bandpass, Lowpass, Notch Filters
- Low Power Consumption, Single 5V Supply Clock Tunable Filters
- Tracking Filters

DESCRIPTION

The LTC1061 consists of three high performance, universal filter building blocks. Each filter building block together with an external clock and 2 to 5 resistors can produce various second order functions which are available at its three output pins. Two out of three always provide lowpass and bandpass functions while the third output pin can produce highpass or notch or allpass. The center frequency of these functions can be tuned from 0.1Hz to 35kHz and is dependent on an external clock or an external clock and a resistor ratio.

The LTC1061 can be used with single or dual supplies ranging from $\pm 2.37V$ to $\pm 8V$ (or 4.74V to 16V). When the filter operates with supplies of $\pm 5V$ and above, it can handle input frequencies up to 100kHz.

The LTC1061 is compatible with the LTC1059 single universal filter and the LTC1060 dual. Higher than 6th order functions can be obtained by cascading the LTC1061 with the LTC1059 or LTC1060. Any classical filter realization (such as Butterworth, Cauer, Bessel and Chebyshev) can be obtained by the appropriate choice of the external resistors.

The LTC1059 is manufactured by using Linear Technology's enhanced LTCMOSTM silicon gate process.

LTCMOSTM is a trademark of Linear Technology Corp.

PACKAGE DESCRIPTION Dimensions in inches (millimeters) unless otherwise noted.

J Package 20 Lead Cerdip

N Package 20 Lead Molded DIP

**10-Bit A/D with Serial I/O
and 8-Channel MUX****FEATURES**

- 10-Bit Unipolar, or 9-Bit Plus Sign Bipolar
- 2's Complement Output Coding on Bipolar Conversion
- 8-Channel MUX with Address Logic
- Built in Sample and Hold
- +5V or $\pm 5V$ Operation
- Reference and Analog Inputs Common-Mode to Both Supply Rails
- Compatible with Industry Standard Full Duplex Serial Interface
- User Selectable MSB or LSB First Data
- 20-Pin 0.3" Wide DIP Package

DESCRIPTION

The LTC1090 is a serial I/O successive approximation A/D converter with the capability of performing either 10-bit unipolar, or 9-bit plus sign bipolar, conversions on any input selected from the 8-channel input multiplexer. The serial I/O is designed to be compatible with the industry standard full duplex serial interface and provides either MSB or LSB first data with 2's complement output coding automatically provided in the bipolar mode. An on chip sample and hold is also included.

A single input address configures the A/D for channel assignment of the 8-channel MUX, single ended or differential inputs, conversion mode (unipolar vs bipolar) and output data format.

**10-Bit A/D with Serial I/O and
2-Channel MUX****FEATURES**

- 10-Bit Resolution
- 2-Channel MUX with Address Logic
- Built in Sample and Hold
- 8-Pin Mini-Dip
- Compatible with Industry Standard Half Duplex Serial Interface

DESCRIPTION

The LTC1091 is a 10-bit successive approximation A/D converter with serial I/O, 2-channel input multiplexer and built in sample and hold all in an 8-pin mini-dip. The serial I/O is designed to be compatible with the industry standard half duplex serial interface.

The 2-channel multiplexer is software configurable for single ended or differential inputs, and the input common-mode range includes both supply rails.

A sample and hold is provided to allow easy, accurate conversion of time varying signals.

PACKAGE DESCRIPTION

FEATURES

- 1 μ Vp-p Noise
- 2ppm Stability
- Low Hysteresis
- Temperature Stabilized
- 0.3ppm/°C Drift

APPLICATIONS

- 7-1/2 Digit Meters
- Scales
- Calibrators
- References

DESCRIPTION

The Super-Zener is a monolithic IC voltage reference designed for exceptionally low temperature drift (0.1ppm/°C), about 1 μ V peak-to-peak noise, and less than 5ppm long term stability. It offers superior performance to the 199 family at the expense of increased circuit complexity and thermal layout considerations.

Included on the die is the reference with temperature compensating transistor, heater for temperature stabilizing and a temperature sensing transistor. All the control and biasing circuitry is external to allow maximum flexibility and best long term stability.

Typical stabilized temperature is about 60°C for best performance although both higher and lower temperatures can be set.

Long Term Stability

7V Reference Circuit

Water Filtration—A water filter is a device that removes suspended solids, bacteria, and other contaminants from water. It is used in a variety of applications, including drinking water, industrial water, and wastewater treatment.

Assembly & End of Line—The assembly and end of line process involves the final inspection and packaging of the product. This process ensures that the product meets the required quality standards and is ready for shipment.

Testing—The testing process involves the evaluation of the product's performance and reliability. This process includes a variety of tests, including functional testing, environmental testing, and life cycle testing. The results of these tests are used to identify any defects or areas for improvement.

Tradability—A tradable unit of work is a unit of work that can be traded between different departments or projects. This unit is used to measure the amount of work that has been completed and to allocate resources accordingly.

Quality and Reliability Assurance Programs

Linear Technology Corporation has a wide ranging program integrating vendor participation, design engineering, and manufacturing to produce the most reliable and highest quality linear integrated circuits available on the market. Our modern manufacturing facility in Milpitas, California is DESC line certified and we have successfully completed over 30 major OEM quality system surveys to MIL-Q-9858 and MIL-I-45208. Our Quality and Reliability Assurance Programs are summarized below:

- **Wafer Fabrication**—A modern class 100 area, modular clean room construction with full environmental monitors. Emphasis is placed on statistical quality control, CV plots, SEM monitors and on our proprietary dual layer passivation system.
- **Assembly & End of Line**—Incoming inspection of all materials and piece-parts, line surveillance and process control monitors.
- **Testing**—Incoming inspection and acceptance of all off-shore lots prior to release to test. Ultra modern LTX testers, multipass testing with closed loop binning to reduce outgoing electrical defective levels. Many "beyond data sheet" tests and full temperature QA lot buy-offs are performed as standard processing.
- **Traceability**—A backside or side mark is placed on all units, where space permits, to give information on a unit-by-unit basis tracing back to the wafer fab lot, assembly, end of line (e.o.l.) and test lots. We consider traceability to be essential for good engineering control and additional insurance for our customers. The information provided exceeds the seal week control required by MIL-STD-883.
- **ESD (Electro Static Discharge)**—A full program is in place from design through manufacturing. Products are fully characterized to MIL-STD-883C (Method 3015) and strict controls on handling and packaging are observed.
- **Training and Certification**—Operator training has been established for all operations and certification is performed on a 6 monthly basis.
- **Major Change Control**—Major change controls are in place to notify our customers in accordance with MIL-M-38510F, LTC internal specifications, or specific customer specifications as required.
- **Quality Assurance**—Full monitoring and reporting of quality data with emphasis on statistical process control charts. Refer to our Quality Assurance Program.
- **Failure Analysis and Reporting**—A formal program exists to record, analyze and take appropriate corrective action on all returns. A report is generated and sent to the customer stating our findings and action.
- **Reliability Flows**—Linear Technology reliability flows include JAN-38510, DESC Drawings, 883 (to the new Rev. C) R-Flow, and Hi-Rel (Source Controlled Drawings). In addition, specialized processing such as SEM, PIND and other tests can be performed as required.
- **Reliability Monitor**—LTC has a unique reliability structure built into each wafer that is used to obtain rapid feedback on reliability. This data is obtained in less than 1 week, versus 40 weeks for a typical reliability audit. See the LTC Reliability Program for more details.
- **Reliability Audit**—Data is gathered on a monthly basis for selected package/product combinations. This data is summarized each quarter and published in a Data Pak showing Operating Life, 85/85, Autoclave, 883 Group C, and 883 Group D summary data. Copies of Data Pak summaries are available by writing or calling Linear Technology, 1630 McCarthy Blvd., Milpitas, CA 95035, (408) 942-0810.

- **ESD (Electro Static Discharge) Protection**—ESD protection is placed into design through manufacturing. Protection is fully incorporated in MIL-STD-883C Method 3015 and strict controls in handling safeguard the integrity.
- **Training and Certification**—Operators working with test equipment for all operations and certification is performed on a bi-monthly basis. Operators are trained on a bi-monthly basis.
- **Major Change Control**—Major change control is in place to notify our customers in accordance with MIL-STD-883C. Customer specifications for specific customer specifications are required.
- **Quality Assurance**—Full monitoring and reporting of quality data with emphasis on statistical process control (SPC) and other Quality Assurance Programs.
- **Failure Analysis and Reporting**—A formal program is in place to record, analyze and take appropriate corrective action on all returns. A report is generated and sent to the customer stating our findings and action.
- **Reliability Flow**—Linear Technology Reliability Flow is a standard flow. DESO Drawing 883 (to the new Rev C) covers both test and DESO Drawing 883 (to the new Rev C) Flow and Hi-Pot (Source Controlled) Drawing. In both cases, equivalent processing such as SEM, FIB, and other tests can be performed as required.
- **Reliability Monitor**—LTD has a unique reliability structure. All data from water that is used to obtain test results is fed into a computer. This data is obtained in less than 1 week versus 40 weeks for a typical reliability monitor. The LTD Reliability Program for more details.
- **Reliability Audit**—Data is gathered on a monthly basis for selected packaged components. The data is summarized each quarter and published in a QAP (Quality Assurance Program) Report. Available: 883 Group C, Drawing: Operating Life Report, Available: 883 Group C, and 883 Group D summary data. Copies of QAPs summary are available by writing or calling Linear Technology, 1630 Westbury Blvd, Milpitas, CA 95035. (408) 942-6800.

Quality and Reliability Assurance Programs

Linear Technology Corporation has a wide ranging history of integrating vendor parts, design, assembly, and testing technology to produce the most reliable and highest quality linear integrated circuits available on the market. Our in-house manufacturing facility in Milpitas, California is ISO 9001 certified and we have successfully completed over 30 major QEM quality system audits to MIL-STD-883C and MIL-45208. Our Quality and Reliability Assurance Programs are summarized below.

- **Water Fabrication**—A modern class 100 and modular clean room construction with full environmental monitoring. Encasement is placed on statistical quality control (SPC) plots. SEM monitors and on-line proprietary dual layer passivation system.
- **Assembly & End of Line**—Incoming inspection of all materials and packages, line surveillance and process control monitors.
- **Testing**—Incoming inspection and acceptance of all components prior to release to test. Ultra modern LXI test, multi-pass testing with closed loop timing to ensure outgoing electrical detection levels. Many "passive data sheet" tests and full temperature QAPs are performed as standard processing.
- **Traceability**—A barcode or side mark is placed on all units, where space permits, to give information on a unit by unit basis tracing back to the water lot, assembly, end of line (e.o.l.) and test lot. We consider traceability to be essential for good engineering control and additional insurance for our customers. The information provided exceeds the seal week control required by MIL-STD-883C.

Introduction

In the early 1960's the study of reliability was mainly the province of mathematicians and statisticians. In the late 1960's and throughout the 1970's it was realized that an understanding of the physical phenomena was necessary to identify the various failure mechanisms and considerable progress was made in this area. Sophisticated diagnostic techniques were devised and this knowledge complemented the earlier theoretical work to form a very sound foundation.

At Linear Technology Corporation we have a firm appreciation for the impact of Reliability on our products and we have made every effort to integrate this knowledge into our device designs and manufacturing processes. We believe that "LINEAR" should be "THE MOST RELIABLE COMPONENTS" and it is our intention to supply "TOMORROW'S RELIABILITY—TODAY"!

All areas that impact reliability have received considerable attention and achieving our goal of "THE NUMBER ONE" Reliability Supplier of Analog Circuits has impacted the DESIGN, FABRICATION, PACKAGING AND TESTING of our products.

"RELIABILITY" requires a total systems approach involving all parties; from the raw material vendor, to the designer, to manufacturing.

Cooperative Interface

Design

At the DESIGN stage the reliability of the circuit is heavily dependent on layout considerations. The thickness and width of the metallization has been defined to minimize the current density and avoid electromigration problems at elevated temperatures. The routing of the metal pattern is designed to eliminate potential inversion, or leakage failures and guard ring structures are used where appropriate. The positions of the bonding pads are carefully selected to optimize device performance and also to fit easily into a variety of packages without creating potential bond loop problems that could result in shorted wires. In all of our voltage regulators, thermal limiting is included in the circuitry to shut down the device if the temperature exceeds a threshold value. Additional insurance is provided by employing short circuit current protection to safeguard catastrophic failure. The philosophy of incorporating fault tolerant designs with innovative circuit concepts is a fundamental design rule at Linear Technology

THERMAL LIMIT CIRCUIT

ISOLATING RESISTOR

Prevents destruction from high transient current in 'Adjust' Pin.

Corporation. The design rules used by Linear Technology are conservative to avoid compromising reliability, and safe operation regions are chosen to prolong device life in the field. Input protection is provided and the ability of our devices to withstand transient voltage spikes is better than average. We focus on reducing lead count of our device designs since there is generally a strong correlation between the number of leads in a package and the mean time between failures for a device. The thermal layout of our circuits is also a major consideration to minimize parameter drift and optimize performance. The designs at Linear Technology Corporation cover a diverse technological base ranging from Bipolar to CMOS. In the case of CMOS, design techniques are used to minimize SCR and latch-up phenomena. Many integrated circuit designs are susceptible to electrostatic discharge effects (ESD) and electrical overstress (EOS) with generally catastrophic results. In the designs at Linear Technology Corporation, care is taken to ensure that a high degree of protection is built into our products to minimize this effect.

Diverse Range of Processes

1. Super Beta Structure
2. Bi-fet Structure
3. Silicon Gate CMOS Structure

Prior to release, new devices are thoroughly characterized and subjected to rigorous mechanical and electrical stress testing to exercise all facets of the design, process, and package combination. Linear Technology Corporation has an active in-house ESD (Electrostatic Discharge) program to prevent yield loss and the potential weakening on devices.

Wafer Fabrication

In the WAFER FABRICATION area the key to a reliable process is consistency and repeatability. Linear Technology has a brand new ultramodern wafer fabrication facility and wafer handling has been kept to a minimum. Cassette to cassette transfer is used extensively and proximity mode aligners are utilized in masking to significantly reduce photomasking defects. Microprocessor controlled furnaces are used to eliminate the impact of operator error.

Cassette to Cassette Transfer

Canon Proximity Aligner

Stringent incoming inspection checks are made on the raw silicon wafers and masks used in the process. Environmental monitoring of the gases, clean air, particle count, deionized water, and furnace temperature and flows are done on a routine basis to avoid any sudden changes that could impact device reliability.

Quality Control checks at various points in the process ensure consistency and control charting is used extensively throughout the fabrication area. The quality of the oxide is checked regularly using C-V plots to check for contamination and surface state anomalies and processes are not operational until minimum requirements are met. Each wafer contains diagnostic structures in addition to the device structures and these test vehicles are used to investigate and detect potential yield and reliability hazards in advance. Scanning electron microscope pictures are taken periodically to check the integrity of the metallization system. Emphasis is given to the early detection of step coverage or misalignment problems. A proprietary passivation system has been developed that will enable

our die to operate in a variety of plastic packages and the nature of this unique multilayer system will make the die virtually impervious to the packaging medium.

The strategy of Linear Technology in developing its process is to make the chip as impervious as possible to moisture and ionic contaminants. This approach assures reliable operation even in marginal environments. The Linear Technology process offers several layers of protection. 1) Extensive CV monitoring of all diffusion tubes and deposition systems assure underlying oxides with low levels of positive ionic contamination. Phosphorous gettering ties up these ions in an inactive state. 2) A proprietary deposited oxide gives conformal coverage of metal and oxide steps, and is free of cracks. 3) A plasma nitride overcoat protects the die from external ionic contamination during handling, testing and assembly. The dual nitride/oxide layer is completely free of cracks and pinholes which enhance corrosion protection against moisture contamination.

RELIABILITY ASSURANCE

Packaging

The impact of new equipment, techniques and materials have had a tremendous impact on device reliability. In the area of wafer scribing, sawing of the wafers has decreased device chipping and cracking significantly. The handling of dice at second optical inspection and die attach is now mainly semi-automatic, removing the need to use tweezers and the resultant damage due to this operation. Semi-automatic lead bonding machines have produced tremendous gains in productivity but as importantly more consistent lead bonds have resulted from this new innovation. Die attach materials have improved and modern low temperature glass ceramic seals have dramatically increased product reliability. At Linear Technology we are using the latest state-of-the-art assembly equipment and materials. Our epoxy material has the lowest sodium and chlorine content of any molding compound available and the data on operating life, power cycling and pressure pot is outstanding. All materials are inspected to better than industry standards prior to use and strict QC

checks are performed on-line to assure control and conformance to specifications. At LTC traceability to a fabrication lot is considered to be of primary importance. On all packages where space allows a side mark or a backside mark is used to give this key information. We are able to track the country of origin, assembly location, die type, wafer fab lot, exact seal dated and also identify non standard processing if required on a special flow. This unique benefit is offered as a standard feature at no additional cost and adds immensely to the level of control and traceability on Linear Technology products.

Mil-Standard 883 Method 2010 Condition B visual criteria are applied to all Linear Technology products and a thorough inspection of all lots received from our assembly operations in Southeast Asia is performed prior to testing. A system of effective and rapid communications exist between our operation in Milpitas, California and Southeast Asia to analyze and correct any assembly or process related problems before the product is shipped to the customer. Precautions are taken throughout the assembly process to minimize the impact of ESD (Electrostatic Discharge) on our devices.

Wafer Saw

Die Attached and Wire Bonded Unit

Encapsulated and Finished Unit

Side/Backside Mark on Unit

Test

The testing of analog circuits is a science in its own right and requires very special technical skills to overcome the challenges that are presented. At Linear Technology we have invested in the very latest "state-of-the-art" computer controlled testers and our device designs exercise the limits of these excellent testers. All Military 883 products receive a 150°C burn-in prior to test and full temperature testing is performed. Regulator products are put on "rack burn-in" and the devices are exercised in the thermal shutdown mode prior to testing. This pretest burn-in contributes to the removal of infant mortality failures and enhances product reliability. Other tests check the thermal regulation and verify the integrity of the die attach as the presence of voids under the die for a regulator affects device performance adversely. Often, tests additional to the data sheet tests are added to a test flow to detect potential flaws that could impact reliability.

LTX/LINEAR Tester with Environmental Handler

At Linear Technology we believe that the thorough and complete testing of our components is an essential element in our plan to provide 'premier' reliable products. Precautions are taken throughout test to safeguard our devices from the insidious effects of ESD (Electrostatic Discharge). As an example, all chip capacitors are pre-stressed with voltages (in excess of the device maximum voltage ratings) to induce failure in substandard lots.

Rack 'Burn-in' of TO-3 Regulators

Burn-in Operation

RELIABILITY ASSURANCE

Reliability Flow

Reliability failure rate can be broken out into three main categories: 1) Infant Mortality, 2) Freak Failures and 3) Long Term Failures. Short term burn-in screening as described in the previous section address the first category—infant mortality. The long term failures represent a significant number of hours in terms of the mean time between failures and so the major area of concern is a sufficient pre-screen conditioning to eliminate the bulk of the infant mortality and freak failures.

These early life failures impact customer warranty costs and reputation severely and the replacement costs are

clearly several orders of magnitude greater than the initial component costs. The Linear Technology 883 program addresses this requirement and offers a cost effective in-house flow. The flow is defined in our MIL-STD 883 brochure and the essential elements of the program include visual inspection at second and third optical inspection to Condition B (Mil-Standard 883, Method 2010, stabilization bake at 150°C, temperature cycling from -65°C to 150°C, constant acceleration, fine and gross leak, followed by a 125°C burn-in for 160 hours or equivalent. Assuming an active energy of 1.0ev, this burn-in is equivalent to 80,000 hours or approximately 9 years at a normal operating temperature of around 55°C.

Typical Representation of IC Lot Failure Rates at 50°C Operation

1. Infant mortality population which could be 0.5% of the lot. Its mean life could be as low as 50 hrs.
2. The freak population could represent up to 5% of the lot. Its mean life could be 5 yrs.
3. Main population whose mean life could be hundreds of years.
4. The dramatic impact on total lot reliability that is achieved by weeding out early failures via 100% burn-in.

Failure Rate vs Time—LT07H

Operating Life Drift Data

Wafer Fab Reliability Audit

As an additional reliability control, Linear Technology has innovated a periodic reliability audit of the wafer fab process, using a specifically designed reliability structure which is stepped into all wafers.

This structure is optimized to accelerate, under temperature and bias, the two most common failure mechanisms in linear circuits, namely mobile positive ions and surface charged-induced inversions. The three-terminal structure is scribed from a run and assembled in a hermetic package. These devices are burned-in for a predetermined temperature and time. The same structure becomes sensitive to either failure mechanism depending upon the bias scheme used during burn-in. A limit is defined for the leakage current change during burn-in; a failure indicates a

wafer fab problem which will be addressed by the process engineering group. The use of a test pattern allows any device to be monitored and also gives faster unambiguous feedback than is normally achieved by performing reliability testing on assembled product. Reliability data is generated in less than one week giving immediate feedback on device reliability. The standard industry monitoring schemes typically take a minimum of 22 weeks to obtain this feedback and it is not uncommon for the cycle time to be up to 40 weeks before fab is alerted of a problem.

Linear Technology utilizes this new control technique in addition to the conventional reliability audit on randomly pulled finished product.

Conclusion

At Linear Technology Corporation we are addressing reliability and quality with the same priority to produce the best possible product in the analog world. We believe that the combination of our extensive design skills, and exciting innovations in the wafer fabrication process, coupled with the most modern assembly techniques, has produced the "MOST RELIABLE" linear products available in the market today. Our standard product flows include thermal

limit rack burn-in (for all regulators) and 150°C burn-in for Military 883 products to significantly reduce the infant mortality failures. In addition, our 883 flow is designed to further enhance product reliability. We fully realize that the cost of failure in the field is many orders of magnitude more than the initial component cost. By purchasing Linear Technology Corporation's products, worthwhile insurance can be gained.

LT07H—Mean Time Between Failures

At Linear Technology Corporation our overriding commitment is to achieve Excellence in Quality, Reliability and Service (QRS). We interpret the word "excellence" to mean delivering products that consistently exceed all the requirements and expectations of our customers. The commitment to QRS extends from the President to every employee, from design to product qualification, and from manufacturing to shipping. To meet this commitment, Linear Technology has established a comprehensive program called "Quality for the Eighties."

This program is divided into four separate, but highly interrelated programs, namely Quality Environment, Total Quality Control, Vendor Participation, and Focus for the Eighties.

Quality Environment

This first program, Quality Environment, serves as the building block for three other programs. It entails establishing an environment that is conducive to the participation of each and every employee in helping to build quality into our products. This program encourages every employee to identify any quality problem and participate in recommending solutions.

Quality for the '80's

An operator training and certification program has been established that covers every area of manufacturing from incoming raw material inspection, wafer fabrication, assembly, and test to shipping. Emphasis is placed on compliance with specifications, performance to quality goals, electrostatic discharge damage (ESD) awareness and controls, encouraging operators to think quality and recommend quality improvement ideas.

To ensure compliance with specifications, a Quality Audit Team performs a systems audit of key manufacturing areas at periodic intervals. Compliance with process specifications and the detailed programs of the Corporate Quality Assurance Policy are verified, and discrepancies reported for quick resolution with special emphasis to eliminate recurring problems. The performance of each area is then rated, providing a strong incentive for each area to excel.

With the philosophy that each department, starting from incoming raw materials, is considered a customer of the preceding department, every effort is made by working closely together to meet or exceed our end-customer requirements and goals.

Systems Quality Audit-Tracking Recurring Problems

QUALITY ASSURANCE PROGRAM

Total Quality Control

The second program starts with the incorporation of innovative, but conservative, design and layout rules to achieve the best performance without sacrificing quality and reliability. During the design and development cycle, Design, Product, Package, Manufacturing, Quality and Reliability Engineering groups participate in design reviews to ensure that all program aspects are covered; ranging from product performance objectives to ensuring reproducibility and repeatability in wafer fabrication and assembly. Special emphasis is placed on devising input protection circuitry to minimize susceptibility to voltage spikes and ESD, optimizing thermal layout to minimize parametric drift, and optimizing bond pad layout to maximize assembly and electrical test yields, at the same time allowing the die to be assembled in a wide selection of packages.

Once the design is approved, a stringent manufacturing qualification test plan is conducted on the initial engineering runs. The test plan is selected to bring out any weaknesses in the design and any manufacturability problems, and includes reliability stress tests such as high temperature operational life and high temperature humidity bias 85°C/85% RH for plastic packages, and MIL-STD-883C

method 5005 qualification testing for hermetic packages. Product performance on these tests must be equal to or better than similar products within the same generic group to be considered qualified. Major design, package, material and process changes are also subjected to these same stringent qualification requirements. In addition to achieving the required reliability performance, an engineering change must also achieve manufacturing yield and quality performance levels equal to or better than the original product to be considered qualified.

In manufacturing, process controls start with vendor qualification on raw material piece parts. A Qualified Vendor List is maintained and performance of each vendor is continuously monitored on a Vendor Rating Program. A dimensional, visual, functional and, where applicable, compositional analysis is performed on each direct raw material lot. Automated state-of-the-art wafer fabrication, assembly and test equipment, cassette-to-cassette handling in wafer fabrication and automated handling in assembly are utilized, where possible, to maintain manufacturing consistency and quality. Only fully trained and certified operators are allowed to work on production material.

Raw Material Controls

SEM Monitor of Metallization Quality

Stringent process controls, typically beyond industry standards, are established for each critical manufacturing step in wafer fabrication, wafer test, assembly, package finishing, mark and pack and shipping as depicted in the Quality Control Flow Diagram. The process controls include monitors of critical assembly processes at a minimum frequency of four times per shift, and lot acceptance inspection for operations requiring 100% production inspection. Initial die inspection and preseal visual inspection are performed per MIL-STD-883 Method 2010 Test Condition B. Statistical quality control techniques are employed in optimizing process parameters, and monitoring process performance through the use of control charts with action limits and upper and lower control limits, and in parametric distribution analysis at electrical test.

Electrical quality is guaranteed by conservative guardbanding on production test programs of a minimum of three machine guardbands, by using state-of-the-art test equipment and 0.04% AQL for lot acceptance testing at 25°C for all military and commercial lots. All lots also receive a QA AQL lot acceptance test at the high and low temperature extremes of the specification. Additional tests, like rack burn-in, beyond the data sheet specifications on regulator products are performed by exercising the parts in a thermal shutdown mode. These tests are incorporated into the test flow to improve reliability and weed out infant mortality failures. Visual and mechanical quality is optimized by minimizing handling of parts in assembly, test and end of line operations. Lead finish processes have been selected that minimize solderability

problems and all lots are subjected to a stringent major visual/mechanical inspection. Administrative errors due to mixed and wrong parts are minimized by strictly adhering to a one lot per station policy, and double checking orders at order entry and shipping. Before shipment of a lot to the customer each lot is inspected to ensure that it meets internal and customer specifications and purchase order requirements. The level of attention paid to each unit is demonstrated by the fact that each unit is traceable to the wafer fabrication lot number via a side or back mark on both 883 and commercial products on all packages, except where there is a physical constraint.

Through the use of automated equipment, strict process controls (utilizing proven statistical quality control techniques), periodic systems and quality audits (conducted by the Quality Audit Team), stringent facilities and environmental controls and monitors, Linear Technology is able to ensure quality is built into the product and to guarantee a consistently high quality level.

The manufacturing quality controls are complimented by a reliability audit program designed to weed out design, fabrication, packaging and assembly deficiencies. Additionally, controls are supported by a comprehensive failure analysis and corrective action program designed to provide timely feedback of findings to all operating groups for resolution. The analysis of customer returns, and corrective action taken, completes the closed loop of our Total Quality Control program.

Vendor Participation

The requirements of high quality raw materials for integrated circuit manufacture range from ppb (parts per billion) impurity levels for electronic grade chemicals to ppm (parts per million) defective levels for lead frame packaging materials. It is not only essential, but critical for the semiconductor manufacturer to work closely with their vendors to attain the high quality levels needed in raw materials. At Linear Technology, a program has been established and implemented to allow vendor participation in formulating specifications and establishing percentage defective and lot rejection rate goals. This vendor participation ensures that the direct and raw material quality levels received are consistent with our manufacturing and end-product quality goals. Clearly, achieving optimum quality product requires the use of the best possible materials available and with continuous communication and feedback from our vendors to improve in this key area.

Focus For the 80's

The following key quality improvements programs have been established to meet the quality requirements of the 80's.

PPM Goals

As demand for quality semiconductor components becomes increasingly more stringent, the percentage goals from the 1970's have given way to ppm goals in the 1980's. At Linear Technology, ppm quality goals are established for every major operation, from incoming inspection to customer returns. Performance to goals is reviewed quarterly and, where goals are not met, quality improvement programs are defined and implemented. Quality goals are updated and tightened on an annual basis, and quality programs are redefined to achieve the new goals established. One of the early benefits of this program is demonstrated by the excellent average outgoing electrical quality (AOQ).

Statistical QC

The increased reliance on automated manufacturing and test equipment underlines the need for strict process control techniques. Statistical QC is a valuable tool and, at Linear Technology, we realize the importance of these methods. Engineering analysis is performed regularly, using SQC techniques to establish the process capability. Control charts showing $\bar{X}$ and R points are tracked to ensure the process is within normal limits and action and shut-down limits are established for critical operations.

QUALITY ASSURANCE PROGRAM

ESD Control

A comprehensive ESD control program has been established which encompasses design, handling, testing, storage, and final packaging for shipment. The program includes the use of grounded table tops, floor mats, wrist straps and heel straps, topical antistatic treatment of floor coverings, banning of static bearing materials from the manufacturing environment, ionizers, and use of conductive or antistatic materials for handling and final packaging. Areas where ESD control must be enforced are designated as ESD Protected areas. ESD awareness training programs help to increase the operator's awareness for successful implementation of this program. Every effort is made to stamp out this silent chip killer. The benefits of this program are improved quality and reliability to the customer.

Quality System Surveys MIL-Q-9858 and MIL-I-45208 Approval

Based on the foregoing quality programs, Linear Technology Corporation is positioned to continuously improve our product quality and exceed the demands of our customers in the 80's and beyond.

Customer Ship-To-Stock Program

Linear Technology is working hand-in-hand with customers to supply consistently high quality-level products to help achieve a ship-to-stock program by eliminating the need to do an incoming inspection. We recognize the benefits to our customers of a ship-to-stock program, namely savings in the need to purchase and maintain incoming test equipment, savings in the need to maintain a safety stock in case of incoming lot rejections, and reduction in board failures and re-work costs because of higher component quality.

Ship-To-Stock Program Flow

Quality Control Flow Diagram

Linear Technology R-Flow

Reliability has been a key focal point at Linear Technology Corporation since our inception in 1981. Our standard product reliability is monitored closely and we have generated an extensive reliability data base for both hermetic and plastic devices. This data is published on a quarterly basis and we are seeing very low reliability failure rates in the 1 to 3 FIT range at 55°C.*

*Note: 1 FIT = 1 failure in 10^9 device hours.

In response to customer requests, we have added an even higher level of reliability screening for commercial hermetic and plastic components. LTC's R-Flow adds an equivalent 160 hours 125°C burn-in to the standard commercial process flow. Following burn-in, a 100% room temperature test is performed and a 10% PDA (Percent Defective Allowed) is applied. This PDA limit affords an additional level of insurance on a lot-by-lot basis and prevents the occasional disparate lot from being shipped for critical applications. The additional room temperature insertion also decreases the probability of any electrical defectives in the R-Flow lot.

R-Flow for Plastic Dual-In-Line Packages

Introduction

As integrated circuit technologies achieve higher speed, smaller geometries, lower power and lower voltage, there is a tendency toward greater ESD (Electrostatic Damage) susceptibility. State-of-the-art CMOS ICs can be susceptible to as little as 50V, a static level that is way below the 500V to 15,000V commonly found in an ESD unprotected work environment. As these state-of-the-art ICs get designed into systems, the ESD susceptibility of system hardware also increases proportionately. Industry estimates of losses due to ESD are in the range of a few billion dollars annually.

It has become increasingly important for semiconductor manufacturers and users of semiconductor and other electronic components to fully understand the nature of ESD, the sources of ESD, and the impact on quality and reliability to effectively deal with this silent chip killer.

Linear Technology Corporation has successfully undertaken a simple but effective ESD Protection Program as part of an overall program designed to enhance product quality and reliability.

The objective of this tutorial is to provide increased ESD awareness by identifying the sources of ESD in the work environment and recommending keypoints for the successful implementation of an ESD program in your company.

The end result of a successful ESD program is the reduction of line failures, final inspection failures and field failures, improved manufacturing yields, improved product quality and reliability and lower warranty costs. We believe that an ESD Protection Program must be an important integral part of every electronic company's product quality and reliability program.

AN1 Understanding and Applying the LT1005 Multifunction Regulator

This application note describes the unique operating characteristics of the LT1005 and describes a number of useful applications which take advantage of the regulator's ability to control the output with a logic control signal.

AN2 Performance Enhancement Techniques for 3-Terminal Regulators

This application note describes a number of enhancement circuit techniques used with existing 3-terminal regulators which extend current capability, limit power dissipation, provide high voltage output, operate from 110VAC or 220VAC without the need to switch transformer windings, and many other useful application ideas.

AN3 Applications for a Switched-Capacitor Instrumentation Building Block

This application note describes a wide range of useful applications for the LTC1043 dual precision instrumentation switched-capacitor building block. Some of the applications described are ultra high performance instrumentation amplifier, lock-in amplifier, wide range digitally controlled variable gain amplifier, relative humidity sensor signal conditioner, LVDT signal conditioner, charge pump F to V and V to F converters, 12-bit A to D converter and more.

AN4 Applications for a New Power Buffer

The LT1010 150 μ A power buffer is described in a number of useful applications such as a boosted op amp, a feed-forward, wideband DC stabilized buffer, a video line driver amplifier, a fast sample-and-hold with hold step compensation, an overload protected motor speed controller, and a piezoelectric fan servo.

AN5 Thermal Techniques in Measurement and Control Circuitry

6 applications utilizing thermally based circuits are detailed. Included are a 50MHz RMS to DC converter, an anemometer, a liquid flowmeter and others. A general discussion of thermodynamic considerations involved in circuitry is also presented.

AN6 Applications of New Precision Op Amps

Application considerations and circuits for the LT1001 and LT1002 single and dual precision amplifiers are illustrated in a number of circuits, including strain gauge signal conditioners, linearized platinum RTD circuits, an ultra precision dead zone circuit for motor servos and other examples.

AN7 Some Techniques for Direct Digitization of Transducer Outputs

Analog-to-digital conversion circuits which directly digitize low level transducer outputs, without DC preamplification, are presented. Covered are circuits which operate with thermocouples, strain gauges, humidity sensors, level transducers and other sensors.

AN8 Power Conditioning Techniques for Batteries

A variety of approaches for power conditioning batteries is given. Switching and linear regulators and converters are shown, with attention to efficiency and low power operation. 14 circuits are presented with performance data.

AN9 Application Considerations and Circuits for a New Chopper-Stabilized Op Amp

A discussion of circuit, layout and construction considerations for low level DC circuits includes error analysis of solder, wire and connector junctions. Applications include sub-microvolt instrumentation and isolation amplifiers, stabilized buffers and comparators and precision data converters.

3rd Qtr '85

AN11 Designing Linear Circuits for 5V Operation

This note covers the considerations for designing precision linear circuits which must operate from a single 5V supply. Applications include various transducer signal conditioners, instrumentation amplifiers, controllers and isolated data converters.

4th Qtr '85

AN12 Circuit Techniques for Clock Sources

Circuits for clock sources are presented. Special attention is given to crystal-based designs including TXCOs and VXCOs.

3rd Qtr '85

AN13 High Speed Comparator Techniques

The AN13 is an extensive discussion of the causes and cures of problems in very high speed comparator circuits. A separate applications section presents circuits, including a 0.025% accurate 1Hz-30MHz V to F converter, a 200ns 0.01% sample-hold and a 10MHz fiber optic receiver. Five appendices covering related topics complete this note.

4th Qtr '85

AN14 Designs for High Frequency Voltage-To-Frequency Converters

A variety of high performance V to F circuits are presented. Included are a 1Hz to 100MHz design, a quartz stabilized type and a 0.0007% linear unit. Other circuits feature 1.5V operation, sine wave output and non-linear transfer functions. A separate section examines the trade-offs and advantages of various approaches to V to F conversion.

4th Qtr '85

AN15 Circuitry for Single Cell Operation

1.5V powered circuits for complex linear functions are detailed. Designs include a V to F converter, a 10 bit A—D, sample-hold amplifiers, a switching regulator and other circuits. Also included is a section on component considerations for 1.5V powered linear circuits.

AN16 Unique IC Buffer Enhances Op Amp Designs, Tames Fast Amplifiers

This note describes some of the unique IC design techniques incorporated into a fast, monolithic power buffer, the LT1010. Also, some application ideas are described such as capacitive load driving, boosting fast op amp output current and power supply circuits.
